At 432 mhz, I had better luck with the 300 ohm TV line,
than I did using mediocre CATV cable and a balun.
This was feeding a UHF TV antenna that I used for ATV
on 70 cm. The 300 ohm line had the lower loss of the two.
Until it rained.. Then it was blackout time until it dried.
I have 300 ohm line feeding a 40 m dipole strung up in
the attic. It's an emergency antenna, and I use the 300
ohm line and a tuner to work any band 40-10m.
Being as it never gets wet, it works out pretty well.
300 ohm TV line is usually pretty good. Until it gets wet. :(
In the real world, I generally prefer coax. On the HF bands
it's about all I use. But the 70 cm ATV antenna was one
case where it paid to use the TV line vs coax. Or at
least the coax I had on hand.. Which was Beldon duo-shield
RG-6 type 75 ohm CATV cable.
Going by a gut hunch, I'd say the twin lead is probably
better than mediocre coax on 1296 mhz. You would need
some fairly high quality coax to equal the loss performance
of even cheap 300 ohm line on 1296 mhz. Or I would think
anyway, judging by it's use on 70 cm. I would think the
advantage would become more lopsided towards the 300 ohm
line, the higher in frequency you go.
I could look up the appx numbers in a book, but I'm too
lazy to get up out of my chair. :/

Thanks Geoff. We do plan on getting weather fax on the computer too (we have a pactor modem and sailmail subscription) but since we had the older separate fax machine we thought it would be good to have it running as a backup. So thank you for all the options.

What indicates the DC meter close to transmitter between the antenna and
ground?
S*

Tom, if he using "an Icom AH-4 Antenna Coupler" on 1296, he's got more
problems than 300 ohm twinlead. :-)

Ian,

Here's how results from your approximation formula diverge from more-accurate Zo figures:

But I take it that your picture still applies to single-core conductors,
and very fat conductors at that.

With the feedline I have in mind, S=55mm and d=1.2mm, so S/d=27.5, which
is way off the end of the scale in your picture.

An interesting bit of trivia for the models I created is that the flux coupling coefficient doesn't vary much with turns for a given diameter and coil pitch.

When you make relatively large diameter coils of fine pitch, k is higher, and that creates the conditions for higher loss in shorted turns.

The implication for long loose coils is that k is low, mutual inductance is low, inductance approaches a constant L per unit length etc.

Sensibly, most air cored solenoids operate in the midrange.

Owen

Hello, and just to tack on to the other comments: If the second antenna's presence changes the feedpoint impedance of the first antenna, you can be sure the second antenna is in the induction (close coupling (non-radiating)) field of the first antenna. If the second antenna could be located about 2-3 wavelenghts from the first it would be in the far-field and its contribution to the radiation pattern of the first, if any, would be minimal. Alas, since this might not be practical, perhaps some modeling using NEC/EZNEC prior to antenna installation would allow for some optimum trade-offs regarding parasitic effects introduced by the second antenna with the goal of saving time (and money). Sincerely, and 73s from N4GGO,

I haven't read all the thread.

I always see the diode in series between the antenna and the headphones.

You will get a much louder audio signal if you connect a germanium diode
(1N34) in parallel with the phones.

```
       \/    antenna
        |
        |________
        |       |
        --      O
diode  \/       )    phones
        --      O
        |       |
        |_______|
         |
        ----
         __   ground
          -
```

Is the direction of the diode important?
If yes, where should flow the electrons through the diode?

No.

How many times do you have to be told that before it sinks in?

The diode (plus leads) is much longer than the total movement of the
electrons at RF. Exactly how many electrons are "flowing" through the
diode during each RF cycle?

I'll give you the meter leads and you can stand out there while the storm is approaching and we'll see what the voltage is due to the storm. the dc voltage due to the radio transmitter is still zero.

Just wondering how a few mils of PVC insulation would effect the
permittivity of a couple of 12 guage wires spaced a couple of  inches
apart.

I tried one a few years ago to use when I go camping. Having a hot
shield did prove to be problematic. This also got it retired to the
junk bin. My favorite antenna for camping is an NVIS antenna that
takes the form of a wire Yagi-Uda aimed skyward. All I need to put it
up is a couple of suitably spaced trees.

By "mils", do you mean thousands of an inch? (The rest of your dimensions
are imperial.)

I doubt it would make much difference

The easiest way I know of to assess the effect of the mixed dielectric
environment, is to measure the velocity factor, and use that to infer an
equivalent permittivity (as I noted in my earlier post).

What band?

Care to share any details?  Sounds like something fun to make.

I have two NEC 536300 relays for sale. The specs are:

50 ohms input and output
150 Watts to 470 MHz
VSWR 1.25:1
Crosstalk 40 dB
12 VDC coil
Shown in August 1965 VHFer if you still have it. I don't.

They can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz   click on photo to enlarge it.

I'm asking $10 each plus shipping.
===
I have a Heath HM-2102 VHF SWR meter 50-160 MHz
0-25 and 0-250 watts. Very good condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz   click on photo to enlarge it.

the diode causes an imbalance, not the transmitter.  it can be either
direction depending on the orientation of the diode... how does your
electron flowing explain that?

You must do the next progress. The simplest radio is like a photocell. There
are the two copper plate with the semiconductor between. Electrons always
flow from the side exposed to light to side in shadow. Never in opposite.
One plate is as an antenna and the other as the chassis.
Do you agree?

There is an alternate electric field between the antenna and earth.

Electrons will move down through the earphones and up through the diode.

This is where I got the idea, Lots of other info on various designs
just by googling NVIS antenna. I usually do 40M as the antenna for 75M
is often impractical to put up but I have one just in case. There is
one place I could probably put up one for 75 over a pond.

Jimmie

Dear John: As others have said - expect a lot of coupling. However, even a second read did not disclose what you wish to place on a 40 foot tower - or if you expect to use the new tower as the end for one or more wires.

Clearly the example of a 3 element 40 meter beam at 40 feet makes no sense.

don't take him seriously... he has a very warped idea of how
electromagnetic waves work.  i just keep him talking to see what funny
ideas come out next.

You should put the meter in series with the diode or the earphone, not in series with the antenna or the earth.

In the diode and in the earphones you have direct current that the meter will measure, in the connection to the antenna and the earth, you have radio frequencies that the meter will not measure correctly.

I have a 105' tower with a cluster of yagi's on top. There are various fixed-direction yagi's bolted to it, along it's height. There are 17 runs of feedline that come from the tower to the shack. I've always wanted to install something vertical for 160m use in the quiet winter months. The 1st and 2nd layer of guy wires are un-insulated from ground/tower. The top guy wires are broken into full 40m sloping dipoles and are remotely switched. Due to all of the other rigs running at the same time and the amount of feedline entering the shack, I don't think I want to shunt feed the tower for fear of getting loads of RF in the shack (had a friend who tried this and was never able to fix the problem with RF in the shack). Here's my question:

- Can I use insulative side-mount brackets and string a vertical up the side of the tower, seprated from the tower by a few feet, and get any kind of decent vertical antenna performance out of this? I was thinking of maybe 5' off the side of the tower, running a wire up to 105', then shoot the other 30 or so feet of wire off and fold it back down and outward at 45 degrees or so. Feed it at the bottom, and install a ground field aound the base of the tower.

I realize there will be some coupling to the tower, but don't have any way (or know how) to model this. Can anyone help with a model to determine approximately how much I'll have to compensate wire length for couplng and top foldback? Have any of you done this before?

Thanks,
ave WB4IUY

a simpler method is to put an insulator at the top of the tower and
run up at an angle so its 20' or so away from the tower at the
ground. the further away from the base of the tower the less coupling
and the more wire there will be going up... and the more art will like
it!

Thanks for your advice! The more views I get, the less likely it is for me to make bad decisions.

Here is where my thinking is now:

I need to put the second tower wherever it will be most useful to my purposes. The existing vertical array and its radials are expendable. It can be reconstructed if desired at another time. I believe it has served my purpose and it is time to move on. Installing a tower is not a trivial matter and the decisions should be made to take advantage of the opportunities it provides.

My interests are a little different than most Hams. I enjoy studying more than operating. Building and using antennas is an important part of the hobby (addiction?) to me. When I made the retirement move to this location I made certain that I would be able to pursue that path. I have enough real estate, wife does not care what I choose to do with the hobby, and the neighbors are indifferent as well! I consider all the antennas to be temporary and everything must be accessible. Twice this past week I have lowered the existing Tribander to 25 feet because of weather forecasts. Change is the rule rather than the exception!

If I encounter excessive interaction I will just consider it another condition to explore. I started out with the idea that this would be a 30 foot VHF-UHF structure but it appears that I can reach a little higher and stronger than that.

I will keep the options open as best I can to provide a second structure that lends itself to further experiments.

At least that is what I am thinking today...

Hello All

I have the above Beam using a switch box Dosy A-SW-4 Vert-Horz-Aux-
Vert/Horz and my coax Belden 9913U. My question is does anybody know
how to setup Circular Polarization when the switch is on the Vert/
Horz. I have one length each of 9913U coming from Vert and from Horz.

All help is greatly appreciated
Thankyou
Terry

EZNEC will do that. A quick look says that it will work just fine.
There's not much difference in feeding the tower and feeding a wire
parallel to the tower.

And yet they have nothing to do with EM waves.

Sorry, I forgot.  You don't believe in EM waves.

What's it like to live in a fantasy world?

tom

You are living in the fantasy world.
To stop it is enough to measure the ground current.

i measure no ground current from a transmitter, so i must not be
having a fantasy.

give me a number... i have 6 transmitters running 1500w rf output each
into 50 ohm antennas.  There is one ground cable to all the stations,
how much dc current should i measure in that ground cable?  show work,
extra points for neatness.

Everybody know that Tesla coil is pumping the earth's charge (pulsatory
flow). The same do yours 6 transmitters.

Stop writing and try to detect it in your ground cable. In the Warshaw LW
mast it would be easy. But it collapsed.

Browsing thru E bay I came across a 1kw
antenna tuner for sale from Cyprus.Now in my younger days I got hold
of one of these and intended to salvage a Icom AH2 to somehow make it
remote since I use Icom radios. After all there are only three motors
that have to be driven! Now I am retired I pulled my old one from
storage after seeing the same on E bay. Question is are there any
kits, salvage ideas out there that would get me going on this long

lost project?
I have never used a external tuner but this seems like a realistic
project to play with.
Of course if there is a unit out there that I can salvage a controller
that is all the better. There are very good photos of this particular
tuner on E bay but like mine it has no controller! I suppose I could
feed a 10 watt signal to it and control the motors by hand to tune but
I do like the idea of automation.
Regards
Art

i have tried, i can't detect it... how much does your theory say
should be there so i know if i am not reading sensitive enough meter.
theories that can't make measureable predictions are not very useful.

why would you need a tuner, isn't your super antenna flat from dc to
daylight?

I knew that was coming!
 My antenna project is finished and active on the grass Now winter is
coming I need another project. I wanted the antenna to pan up and down
for best angle automatically but I am short on ideas. So seeing the
tuner on Ebay reminded me of a project that got away. The antenna has
only been tested down to top band as I am not equipted to go down
lower and the mfj only goes up to 170. I suppose I can take the tuner
to a hamfest but it has been a few years since I went to one. I am
using a window
wiper motor for the up and down  so it would be nice to make that
automatic if more gain is available.

If you get one put together let me know how it works for you . My operation have been very sporatic and I really cant compare it well with anyting. I would think operation would be best when both stations are using NVIS antennas but I have yet to communicate with someone who was doing the same. I have made contacts on this antenna when another antenna an 18ft vertical was just dead quiet, Location was in a campsite in a valley near Boone NC.

OK here is what I know about it. It was a pyramid shaped antenna approximately 20 ft on a side at the base. The antenna was supported by a central mast from the apex of the pyramid and the base of the antenna was suspended about 3 or 4 ft off the ground. Corners of the base of the pyramid were tied off to tent stakes with nylon rope. It was used for HF communication in the range of 4 to 30 Mhz and I the the nomenclature for it was OGTHAGONAL ANTENNA. Thats as much info as I have if anyone could add more I would appreciate it. Is this an NVIS antenna? Manuals would be great. Last time I saw one in use it was being used for HF SSB Air to Ground communication.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

theories that can't make measureable predictions are not very useful.

You have 1500W, LW transmitters 1500kW. But the biggest is the Sun.
Planets have the excess of electrons. Receiver antennas close to transmitter
should also have.
But everywhere are an exeptions (materials dependent). Like with the Hall
effect.

In a ground cable is the pulsatory flow of electrons.
A current meter has the resistor and voltmeter. Try an osciloscop instead of
voltmeter. The voltage should not be symmetric. But I am not an expert.
S*

Electrons are blasted away from the sun by the atomic fusion reactor
at the core. How many RF transmitters run on atomic fusion?

The bottom antenna on the first page of <http://csantennas.com/HF-antenna-systems.htm> is often configured as you describe. The two dipoles are attached to the same center insulator / connector assembly and run at ninety degrees to each other. Forward Air Controllers would use them to direct tactical air support. I own one of these that I acquired in a trade. When I was a zoomy they would be set up exactly as you describe during field communications exercises but I don't know if the intention was to use them as NVIS antennas or not. There was quite a lot of google hits on the spelling that Bill suggested. vis Orthogonal Antenna.

Again a school physics.
The Sun attracts all solids body. They are reworked into plasma.
Oscillations is a by product.

Not only planets. Everything has excess of electrons.
http://www.aerospaceweb.org/question/design/q0234.shtml

And what with your receiving antenna?

It isn't the tuner hardware that is going to be a problem, as much as designing the tuning algorithm that drives the hardware. Mark Johnson did a very good job, reverse engineering the stuff that Bill Shield brought west from Motorola Military back in the 70's for the SEA Autotuners. SGC copied the SEA Firmware & Design enbank, for their stuff. The best stuff, was the stuff Collins did for their Military Autotuners. Starting from scratch is going to be a BIG design project.

Here: http://scitoys.com/scitoys/scitoys/radio/homemade_radio.html

is wrote: "If you don't have a strong station nearby, you can add a battery in series with the LED (a small 1.5 volt battery works fine). The LED will light up, and the radio will play much louder than without the battery (if the LED doesn't light up, try connecting the battery the other way around). This arrangement is the best detector I have used so far, and is louder than the 1N34A germanium diode"

Can anybody check the direction of electrons flow?
Of course between the antenna and the ground.

My problem as far as I can see is that the control for the AH2 is that
the innards are transferable but it only controls two motors where as
my tuner has three.
I suppose I could just use two and not utelise the fine tune inductor.
Will sleep on it for a while and look at the AH4 version or in the
worst case fine tune by hand if necessary. I suspect the fine tune is
not really necessary in most cases other than satisfy the over
zealious swr users

Where did Cecil mention "coherence"?

Another couple questions. Should be easy answers for you.

Since your model supposes that the "plasma" carries the signal, what
does the model predict as the radiation resistance of a dipole in free
space?

Given your model, which you have spoken about at some length but no
depth, why wouldn't your predicted radiation resistance change with
plasma density, contrary to all measurements ever made?

Photons and incoherence are the same. "In 1900, Max Planck was working on
black-body radiation and suggested that the energy in electromagnetic waves
could only be released in "packets" of energy".

In a black body is many dipoles which work with brakes. In radio a dipole
(or monopole) works continously.

They have the kinetic energy. "the energy jump from  electron to electron"
by collisions.

It is a full analogy with the acoustic waves. Molecules are the medium for
acoustic and free electrpns for the electric waves.

It is not my model but Tesla's. Probably he was spoken deeper.
You try to marry Heaviside with Tesla. TEM are not longitudinal.
Longitudinal waves have analogy with acoustic waves.

These two concepts seem to be contradictory. Some simple 1/4WL Tesla
coils are obviously close to 90 degrees long and limited by the speed
of light. The traveling waves cannot travel faster than the axial
propagation factor, whatever that value might be. For those simple
Tesla coils, there is an electrical ~1/4WL between the feedpoint and
the spark. Simultaneity is impossible in the real world.

(Thanks for the email invite, but right now most of my time is
dedicated to learning how to be a square dance caller.)

Stalin had the science writers purge their texts of those qualities that you miss and that we enjoy here in the west (they were condemned as bourgeois inspired perversions with counter-revolution tendencies). Hence you find decrepit pensioners sneering at elitist propaganda (western science) that dismisses the party-approved water models of RF transmission. In the historical perspective, we have to remember this state inspired instruction was learned in an era of RF transmission jammers located in every neighborhood so that trying to hear the VOA or the BBC made things sound like you were listening through the breakers of the surf. Hence the "experience" of the water model was very pervasive and arguing its falsity comes up against the resistance of the old guard.

Long, long ago, I possessed a few copies of some of Teslas' original notes, thoughts, sayings, etc. condensed in a thin little book. I can remember reading it and contemplating what he was thinking/saying. I got a distinct feeling Tesla seen his "magnifying transmitters" and the "receivers" as, on resonance, being connected together by an "invisible wire" ... I still think I may have missed a lot of what he knew/discerned/guessed/thought/etc. He was nothing short of utterly amazing ... possibly "insane like a fox."

BTW. I Square Danced from the time I was ~17 to 26, some of the best times I ever had. Got into exhibition dancing in front of large groups, just for fun ... times were a lot simpler/better then ...

Regards,
JS

Always are the two descriptions. Physical (dynamic) and geometric (kinetic).

"Geometric algebra in the sense used in this article was not developed,
however, until 1844, when it was used in a systematic way to describe the
geometrical properties and transformations of a space
"Nevertheless, another revolutionary development of the 19th-century would
completely overshadow the geometric algebras: that of vector analysis,
developed independently by Josiah Willard Gibbs and Oliver Heaviside. Vector
analysis was motivated by James Clerk Maxwell's studies of electromagnetism,
" From: http://en.wikipedia.org/wiki/Geometric_algebra
>

Tesla's longitudinal radio waves are also described.

For us is enough to know that the transversal are rotational. The geometric
desription of the rotational oscillations is very impressive. It must be in
the school program.

Stokes drift is also impressive. Do you know that the ink printer use it?

So to return to my real world example, an air core solenoid used as a
tuning coil for a bugcatcher antenna, would I be wanting to short the
unused portions of the coil, or leave them unshorted?

Seems that unshorted would be bad.

Movements in 2D are described on the imaginary plane, in 3D by vector
calculus, in more D by tensors.
You need  not know that to analise the radio waves.
But you should know that no pure transversal waves. Always are the two
components.
Heaviside did not know that.

The stub match can be used at hf too.

Using a stub, the balun can be integrated into it as well. A couple of photos of my homebrew 20-meter monoband Yagi demonstrate.

http://k6mhe.com/n7ws/YagiFeed-1a.jpg

http://k6mhe.com/n7ws/YagiFeed-2a.jpg

Note: the antenna is sort of "upside down" as it's on a fold-over tower that was folded over at the time

Given the relatively few turns on a typical bugcatcher, and the low coupling of flux, the voltage rise would be negligible, and the fact that you're not having a high voltage across the coil in the first place (compared to turn spacing), I don't think it's an issue to leave the end free.

Practical experience: On most tesla coils, the primary is a 10-20 turn coil with turn to turn spacing of 1/4" to 1/2" or so and runs at a peak voltage around 20kV. One adjusts the tapping point to adjust the primary L to bring the system into resonance, and it usually winds up being tapped about 70% of the way into the coil. Almost never do you get arcing/corona from the free end of the coil, which is potentially at as much as twice the voltage, and if it were in free space, you'd start to see corona from the relatively small radius of curvature.

Indeed, but some shorted turns intercept more flux than others.
Hopefully the field in the passenger seat is small enough that the power
dissipated in one's spouse's ring is fairly low.

> Seems that unshorted would be bad.

I wrote some notes based on a simple model of an air cored single layer solenoid, they are at
http://www.vk1od.net/tx/concept/TappedCoil/index.htm .

The model suggests that shorting the unused turns is a poorer solution when the flux coupling factor is relatively high, and a very small number of turns are shorted. Poorer both because of loss and the granularity of L adjustment.

In that situation, the voltage induced in open unused turns is not very high, whereas it can be extreme in cases where most of the turns are unused.

So, a combination of methods may be optimimum, depending on the flux coupling factor, voltage withstand, granularity of variation of L, etc.

The Old Guard is often found trying to commemorate the past in
relation to their old heroes:
"In Paris, on August 28, 1844, at the Caf� de la R�gence  on the Place
du Palais he met Friedrich Engels, who would become his most important
friend and life-long companion. Engels had met Marx only once before
(and briefly) at the office of the Rheinische Zeitung in 1842;[28] he
went to Paris to show Marx his recently published book, The Condition
of the Working Class in England in 1844.[29] This book convinced Marx
that the working class would be the agent and instrument of the final
revolution in history."

The faded political trash that is now used as decoupage for today's
arguments is carnival in spirit but is as nutritionally substantial as
cotton candy.

Something sort of like that,- my version would have a box underneath the loading coill where the wires would end up.

As you know I am collecting the evidences. Could you tell me something about the cristal radio?
There is the diode. The electrons flow in the one direction. The questions are:

1. Electron must flow from the antenna to the ground,
2. In the opposite direction.

3. Radio works in the both arrangement.

> The faded political trash that is now used as decoupage for today's

It would be easy to collect the information from the own laboratory. But
asking is the substantial.
S*

Nope, RF electrons don't actually flow. They essentially vibrate in place. "For a copper wire of radius 1 mm carrying a steady current of 10 amps, the DC drift velocity is only about 0.24 nanometer per microsecond." At 10 MHz, the electrons would vibrate back and forth at about 0.01 nanometer per 0.1 microsecond. Consider how large 0.01 nanometer really is so for all practical purposes, electrons don't flow at all at HF frequencies. Electrons at HF are just a bucket brigade for the photons that deliver the RF energy to the diode detector. Unless a circuit is at DC steady-state, photons are involved, i.e. RF involves photons which constitute the RF fields and RF waves.

After taking a good look at the loading coil, its apparent that there isn't much choice. The bottom of the coil is attached to the lower mast, and a four pronged plate that the tap wire is attached to at the same junction. So unless no tap is used, some portion will be shorted/bypassed or the like.

And given that GLA systems is no longer in business, my loading coil just got a lot more valuable, so I'll have to experiment on a new coil. I have the Acrylic top and bottom pieces, next will be getting the rods and make the wire cheannels.

So which would be better (less lossy) for a 75m Texas Bugcatcher coil
used on 40m? Short out each turn individually or use one jumper to
short out all of the turns that need to be bypassed?

>
> So which would be better (less lossy) for a 75m Texas Bugcatcher coil used on 40m? Short out each turn individually or use one jumper to short out all of the turns that need to be bypassed?

Kinda my original question.

Intuition tells me that ideally - in order of preference:

1. the entire unused portion of the coil should just disappear.

2. A shorting sleeve that renders the unused portion of that loading coil as a fatter part of the mast.

3. What I have now, a #12 wire from the top of the bottom part of the mast to the spot that I tuned the antenna. The bottom of the coil is attached to the same point on the bottom mast.

1. is impossible without having separate replaceable tuning coils. Crazy inconvenient.

2. This would be the world's fattest screwdriver antenna.

3. This becomes the question? Is this worth worrying about? And testing would be interesting for each frequency to determine which ones benefit from shorted/non shorted operation.

Which now leads me to ask, what would be a good way to set up such an experiment? I guess if follows on that what exactly is the phenomenon

that I would be witnessing? A transformer effect in unshorted condition
certainly would be a problem even for my transmitting equipment?

I can  not debate your particular area other than to point what I have
in actuality.
By removing all reactance especially the magnetic field the current
flow removed itself from the material and travels on the surface.
This is not unusual as superconductors drop to zero resistance when
the magnetic field is canceled or removed. There are only two
resistances in radiation and if no skin depth is then generated then
the material and its resistance is removed from Maxwell's equations
Now one can question my understanding as to what is happening but the
```

fact is my antenna
swr does not go above 3:1 no matter what band I am on! Yes, by not
understanding what is really happening it would be easy to say "dummy
load " but that is not the real answer.
So I would ask all what exactly is impossible
about the sequence of event that I describe while adding that computer
programs confirm it?
By the way the antenna is sitting om the grass
as height does not affect dish antennas!

Yes, but even better, a new coil optimised for the band. Not an original thought though!

>
> 2. A shorting sleeve that renders the unused portion of that loading
> coil as a fatter part of the mast.

Mike, some thoughts.

A word explanation of what my simple model draws out quantitatively for an ideal coil (meaning insignificant distributed capacitance)...

Just one turn shorted / open...

If you short just one turn at the end of the coil, a current is induced in the shorted turn. The current depends on the flux coupling factor k and the number of turns in the rest of the coil. The loss depends on the current squared and resistance... so whilst the current squared might be high, resistance would be relatively low. Nevertheless, if k is high, then the current induced in that shorted turn will increase total loss significantly. The effect of a large current in the shorted turn is to reduce the inductance of the combination, the higher the current (high k), the greater the reduction in inductance.

If on the other hand, that one turn was left open a voltage is induced in the open turn. The voltage depends on k and the number of turns in the rest of the coil.

More turns shorted / open...

If more turns are shorted, the induced current is lower, and R is higher, the net effect is that additional loss is reduced. Inductance is reduced, but at a slower rate than intially.

If more turns are left open, the voltage induced in the unused turns increases and could be many times the voltage developed across the used turns. A first approximation is k times the turns ratio times voltage developed across the used turns.

Shorting each of several adjacent turns...

This approach assures the highest circulating current in the shorted turns, assuring the worst loss at all tappings.

Screwdrivers...

The approach taken in some screwdrivers uses a very low resistance shorted turn (the tube) to make contact at the tapping point, and it protects the unused coil turns (now inside the tube) from flux. Done properly, that might well be a fairly good solution... I haven't tried to measure it.

k...

Avoiding high k provides finer granularity of inductance adjustment and lower loss when few turns are shorted... but of course lower k means a physically larger coil for the same inductance, and potentially higher R which increases loss.

Owen

Pick a band.  Pick a time.  Let's have a contact.

I know what the answer will be of course, an excuse why you can't have a
Q with me or anyone else.

But in that situation, the voltage across the unshorted turns is likely
to be low, because you've got low reactance, right? So the net effect is
small.

Hi Jim,

It depends what you take as a reference. A rough estimate of the voltage across the unused turns is the turns ratio (unused /used) time the flux coupling factor, which in practical applications is likely to be in the range 0.2 to 0.5.

If the application was a valve amp pi coupler, the voltage impressed across the used turns could be a couple of thousand volts, and on a 10m tap, the voltage across the unused turns could easily be 5 to 10 times that.

In the case of a loading coil for a multiband whip, the current in the used turns is probably similar from band to band, but the used turns are lower for higher bands and so the flux cutting the unused turns is lower, but there are more unused turns. In this application, insulation problems are probably less severe than the PA with a bandswitch.

To my mind, the interesting thing is why shorting some turns is 'ok', and then to understand that doesn't make it 'ok' in all scenarios. For instance, someone taking a valve amp pi coupler and implementing it on a single powdered iron core changes the situation significantly.

Re the Tee circuit, yes, but it takes a while to draw it up... not nearly as quick as grinding a few numbers and creating a graph! I have a backlog of hand drawing scanned into articles to redraw already.

Owen

Thank you very much for the explanation.

Another interesting and very practical graph would be: for a 20 turn, 50mm diameter and various winding pitches coil, how much additional energy loss, 1, 5, 10, 20, 30, 40 additional short circuited turns add.

Wiki is more usefull than you:
http://scitoys.com/scitoys/scitoys/radio/homemade_radio.html
" Power from radio waves -- hooking up a meter to measure the voltage and
current "

"If you have a good antenna, or a strong radio station nearby, the ammeter
might read more than 50 microamps. If you have a short antenna, you might
get only 5 microamps and still be able to hear the station clearly in the
headphones. I put up a 200 foot antenna between two trees over my house, and
tuned to a 50,000 watt station about 30 miles away, and now I get 175
microamps of current through my meter."

Hello Alejandro,

I think the graphs in the article demonstrate that there is a simple
analytical solution, giving the appropriate parameters.

There are issues about the applicability of the model to the real world,
but the model does show trends about what is desirable and undesirable
practice. Wheeler's formula for inductance has its shortcomings
(Wheeler's formula doesn't take into account wire diameter for instance),
but it is (IMHO) sufficiently accurate to expose some of the
'interesting' effects that prompted your initial question.

The model is based on basic electricity and magnetism, stuff that isn't
so appeallng to new age hams.

Owen

What would you consider the answer to be?
It's really an inefficient toaster oven?

> So I would ask all what exactly is impossible
> about the sequence of event that I describe while adding that computer
> programs confirm it?

You want the Bush or the Obama explanation?

Lets ask both.. Hey Gee Dub, what do you think?

"Son, your misapplication of the modeling programs
have led you astray. Number one, you can't polish a
turd into a diamond. Believe me, I've already tried it
out at the Crawford ranch. Didn't pan out...
Number two, the modeling programs are not coded to
deal with turd polishing. So any results obtained from
misapplying an antenna modeling program to simulate
the performance of a polished turd is bound to end in
frustration and gross error."

Hey Barry, what's your angle?

"I think we should give him a $500.000.00 grant!"

I guess it was a split decision..   :/

> By the way the antenna is sitting om the grass
> as height does not affect dish antennas!

Actually, it does make it easier for the dog to drink
the rain water out of it. Good call!

I prefer Wiki:
"The voltmeter in the same radio reads 125 millivolts. Since watts (the measure of how much power we have) is the voltage multiplied by the amperes, we have 0.000175 times 0.125, or 0.0000218 watts, or about 22 microwatts. The station is putting out 50 killowatts, and we are receiving one ten billionth of that power, yet we can hear it across the room."

Could you help? The simplest radio:
" Tape the other diode wire to a cold water faucet. This makes a good connection to the ground, and is thus called a 'ground' connection.

Hold the remaining free bare wire of the earphone in your hand. This makes your body into the antenna for the radio. Put the earphone in your ear. If you are close to a strong AM radio station, you will be able to hear that station faintly in the earphone. You may hear more than one station at once. "

The diode has the two ends. Which one should be tapped to a cold water faucet?
S*

Same on all bands with the proper coil-taps/whip-sections selected?

well, of course, once you put a diode in the circuit you are forcing
flow in only one direction.  but try this, turn the diode around so it
only allows electron flow FROM the ground... and you will still hear
the station.  so now how do electrons flowing from the remote antenna
through the air get to ground through your diode??

Stephen-

How high is high?  Most modern radios can tolerate SWR up to 3:1.

On a specific band, is SWR high across the entire band?  I understand
```

the Buddipole is fairly critical, especially on the lower HF bands. It may need to be adjusted for the part of the band where you want to operate.

With the same power?

> so now how do electrons flowing from the remote antenna
through the air get to ground through your diode??

You forget about chassis. In the opposite setup the wire is the antenna and
your body is the chassis.

Are you rich enough to check the simplest radio?
Is the same power in the both arrangement?

S*

The fog of ingrained stereotypes lives on long after the Soviet Information Bureau published "Falsifiers of History." Stalin personally edited the book, rewriting entire chapters by hand (how well we experience this here, daily). The book claimed, for instance, that American bankers and industrialists (are you rich enough?) provided capital for the growth of German war industries.

:) Nicely put.

But the moron either won't get it or will deny it anyway. Matters little.

But we all know that there are positrons. So maybe he's right after all.

After a few milliseconds contemplation I've decided to go with not right.

Yes pretty much the same on all bands I think I might have solved my
problem the transceiver was not grounded sufficientally and when I did
this the swr came down on all bands expecting part of 40 is it correct
to say that swr is affected by station grounding ?

Ideally, the coax would carry negligible common mode current and you would not notice such an interaction.

The Buddipole should be used with an effective balun. My preference would be a current balun with a high choking impedance, but IIRC that is not what Buddipole recommend.

Let the coax fall to the ground vertically, and route it away from the antenna at right angles to minimise coupling.

VSWR will be poor on the lower bands (80, 40) if you do not have the variable ratio balun, and set it appropriately.

You are really shy on details (eg we have as good as begged you to quantify 'high'), so you get brief answers. Describing the problem well to yourself is the first step in resolving it.

Owen

If you're interested in the AIM4170 antenna analyzer, you might find my
updated presentation useful:

http://homepage.ntlworld.com/wadei/aim4170.htm

I have no commercial interest in the analyzer -- I am just a very
satisfied user.

Good of you to post that Ian. I'm afraid I missed your lecture- one of
several "clashes" where interesting lectures happened at the same time. It
was almost a case of "toss a coin".

I hope you enjoyed the Convention, we (my XYL and myself) certainly did.

> What percentage of water molecules are moving more horizontally than
vertically for what percentage of the time? That percentage is
certainly pretty small. Even for those normal steady-state waves, it
appears that the vertical motion at the surface is still greater than
the horizontal motion for at least half of the cycle.

Stokes measured the movements. They are shown there:
http://en.wikipedia.org/wiki/File:Deep_water_wave_after_three_periods.gif

Each wave transports a mass. So the movements must be nonsymmetrical in in
direction of propagation.

>*Anywhere except
at the very surface, the vertical motion is obviously greater than the
horizontal motion*. But the subject was a transient tsunami wave where
the horizontal motion is virtually non-existent because of inertia.

If the bottom of the ocean go up than the water is flowing outside this
place. It is a simple flow not a wave.

water flow and water waves are NOT good analogs for electromagnetic
waves. the only common part is that some part of the solution of
their equations includes a sine or cosine function.

:-) The bottom of the ocean going up (and down), i.e. earthquake, is the major *cause* of Tsunami waves. Once set in motion, no further movement of the bottom of the ocean is necessary. The energy in a Tsunami wave extends all the way from the depth of the earthquake source to the surface. Almost all of the water molecule movement in a Tsunami wave is up and down. There is virtually no simple flow in a Tsunami wave since the *energy* is traveling at hundreds of meters per second. If it was "simple flow and not a wave" the energy in the wave would be dissipated in accelerating the water molecules to a velocity of hundreds of meters per second. Hint: Try making a spinning top out of an unboiled egg.

Utter nonsense. "Take our radios ..." and do exactly what? You
never advocated any action. Go away.

Years ago I built a J antenna for 10m. I was actually pleasantly
surprised at how easily it tuned up compared to the 2m versions I had
buit. I checked for feedline radiation by checking for variarions in
VSWR while coupling a large mass(me) to the feedline near the feed
point. Little change was noted. Do the larger versions of this antenna
normally perform better(more predictably)  or was this just a case of
```

dumb luck.

:-) The bottom of the ocean going up (and down), i.e. earthquake, is
the major *cause* of Tsunami waves. Once set in motion, no further
movement of the bottom of the ocean is necessary. The energy in a
Tsunami wave extends all the way from the depth of the earthquake
source to the surface. Almost all of the water molecule movement in a
Tsunami wave is up and down. There is virtually no simple flow in a
Tsunami wave since the *energy* is traveling at hundreds of meters per
second.

"The measured tsunami flow velocities were within the range of 2 to 5 m/s. "
From: http://www.agu.org/journals/ABS/2006/2006GL026784.shtml

>If it was "simple flow and not a wave" the energy in the wave
would be dissipated in accelerating the water molecules to a velocity
of hundreds of meters per second. Hint: Try making a spinning top out
of an unboiled egg.

It is like the soliton.

no, waves can transport energy without mass.  photons have not rest
mass, only energy... look that up in your favorite wikipedia.  sound
waves require mass, but don't have to transport it, just move it back
and forth around a point, thus they move energy without net movement
of mass.

ah, grabbed another non-sequitar term to add to your gibberish now?
for how long will everything be a soliton to you?

Since I built my first 80meter/40meter 6aq5 + 6DQ6 transmitter with pi
output in 1972, when I want to vary the inductance of a coil in a
tunner, or loading coil in an antenna, I just short circuit some turns.
I see that this is the usual practice everywhere.

My question is why do we not just leave the turns open circuited instead
of short circuiting them.

It appears to me that in the short circuited turns, a very big current
must be circulating, adding heat losses and lowering the Q of the circuit.

you are correct.  and if the coil is on a core it can overheat the
core also.  leaving them open also causes problems since it looks like
a transformer with an open circuit it can develop very high voltages
and flash over the band switch.  The best method is to have separate
coils that are not coupled, but that of course gets more expensive and
larger.   better amps have a combination, usually shorting turns on an
air core inductor for the high bands and then adding separate toroids
and capacitors for the lower bands.

an example of what can happen with shorted turns:

For a screwdriver antenna, the problem is solved by a conductive
sleeve over the outside of the shorted turns that keeps most of the RF
on the conductive sleeve instead of in the shorted turns of the coil.

that doesn't really 'solve' it, that just provides a single big
shorted turn instead of many turns.

Good Grief! The deeper the ocean, the faster the Tsunami wave travels. The Tsunami wave slows to a crawl when it reaches land and indeed is forced by the slope of the land to travel horizontally. Unfortunately for your argument, I was talking about the speed of a Tsunami wave in the open ocean which can be as fast as a 757 jet airplane. From:

http://www.enchantedlearning.com/subjects/tsunami/

"The Speed of a Tsunami: A tsunami can travel at well over 970 kph (600 mph) in the open ocean - as fast as a jet flies. It can take only a few hours for a tsunami to travel across an entire ocean. A regular wave (generated by the wind) travels at up to about 90 km/hr."

http://www.infoplease.com/ipa/A0930274.html

"For example, at the deepest ocean depths the tsunami wave speed will be as much as 800 km/h, about the same as that of a jet aircraft. Since the average depth of the Pacific ocean is 4000 m (14,000 feet) , tsunami wave speed will average about 200 m/s or over 700 km/h (500 mph)."

Exactly how much horizontal movement can there be in the water molecules when the Tsunami wave is moving at 800 km/h (200 m/sec)?

Maybe the single big shorted turn IS the solution? :-) When there are
no actual shorted turns, i.e. all of the coil is exposed, does the
bottom section of aluminum tubing become that same single big shorted
turn? In any case, one very conductive and very wide shorted turn is a
lot less lossy than a number of small shorted turns.

Good Grief! The deeper the ocean, the faster the Tsunami wave travels.
The Tsunami wave slows to a crawl when it reaches land and indeed is
forced by the slope of the land to travel horizontally. Unfortunately
for your argument, I was talking about the speed of a Tsunami wave in
the open ocean which can be as fast as a 757 jet airplane. From:

http://www.enchantedlearning.com/subjects/tsunami/

>"The Speed of a Tsunami: A tsunami can travel at well over 970 kph
(600 mph) in the open ocean - as fast as a jet flies. It can take only
a few hours for a tsunami to travel across an entire ocean. A regular
wave (generated by the wind) travels at up to about 90 km/hr."

http://www.infoplease.com/ipa/A0930274.html

> "For example, at the deepest ocean depths the tsunami wave speed will
be as much as 800 km/h, about the same as that of a jet aircraft.
Since the average depth of the Pacific ocean is 4000 m (14,000 feet) ,
tsunami wave speed will average about 200 m/s or over 700 km/h (500
mph)."

>Exactly how much horizontal movement can there be in the water
molecules when the Tsunami wave is moving at 800 km/h (200 m/sec)?

You are an expert. Electric waves travel with"c".
"Exactly how much horizontal movement can there be in the free electrons
when the electric wave is moving at 300000 km/h?
S*

>> Each waves are the same. They transport mass and energy. They never are
> harmonic.
> S*

>no, waves can transport energy without mass.  photons have not rest
mass, only energy... look that up in your favorite wikipedia.  sound
waves require mass, but don't have to transport it, just move it back
and forth around a point, thus they move energy without net movement
of mass.

So read the Wiki:
"For a pure wave motion in fluid dynamics, the Stokes drift velocity is the
average velocity when following a specific fluid parcel as it travels with
the fluid flow. For instance, a particle floating at the free surface of
water waves, experiences a net Stokes drift velocity in the direction of
wave propagation.
More generally, the Stokes drift velocity is the difference between the
average Lagrangian flow velocity of a fluid parcel, and the average Eulerian
flow velocity of the fluid at a fixed position. This nonlinear phenomenon is
named after George Gabriel Stokes, who derived expressions for this drift in
his 1847 study of water waves."

This nonlinear phenomenon is in each real wave. In texbooks are a paper
waves - for kids. They are linear and symmetric.

"just move it back and forth around a point" is a simplification necessary
in schools.

no, it becomes a very small diameter and long shorted turn... but yes, it is a shorted turn. you don't see as much effect because it is smaller in diameter so the self inductance is smaller and it only intercepts a fraction of the flux from the end of the coil.   you get more of an effect if you place an air core coil with its end near the side or bottom of a metallic enclosure, the plate looks like a shorted coil and can have large circulating currents.

> In any case, one very conductive and very wide shorted turn is a

that is why they get away with it, the losses in the big fat thing are low enough that it causes less trouble than shorting turns with a switch or relays.

ah, but that requires fluid flow. electromagnetic waves do not
require fluid flow or they could not travel at c. There may be some
analogous phenomena in plasma where you can get non-linear effects but
they would not propagate at c, they would be at some much smaller
velocity.

Only fairly basic AC circuit theory is needed to analyse the effect of the shorted turns.

If you have a air cored solenoid inductor of n turns, and short m turns at one end, you can treat that as two independent inductors of n-m and m turns with some flux coupling factor k. The mutual inductance can be calculated, and a T equivalent of Ln Lm-n Rn Rm-n M elements constructed and solved. k of course depends on coil construction and n and m, a value can be determined by measurement of the reactance of the combination. (You might be surprised at how low k is.)

Essentially, when the power lost in the shorted turns is low (due to the combination of low k and low R), then the technique works fine.

We (hams) have some pretty inadequate word based explanations for some of these kind of things when there are simple quantitative solutions at hand.

An example is the traditional explanation of link coupling ratios. See http://vk1od.net/tx/concept/lctr.htm for a quantitative explanation using the same techniques as suggested above.

BTW, the solenoid inside an aluminium tube is a case of an inductor surrounded by a single shorted turn... but if R in that turn is very low, then little heat is generated in the tube.

We also sometimes use a movable shorted turn to adjust an inductor... a brass or preferably silver plated brass slug was often used in VHF / UHF tuned circuits.

Owen

Already answered earlier in this thread. For HF frequencies, the horizontal movement of the electrons is minuscule and they can be considered to be oscillating in place. It is the photons that move at the speed of light.

(You might be surprised at how low k is.)

To give a mental arithmetic example...

Assuming ideal inductors for the moment...

Suppose you had an air cored inductor, that when you measure the inductance of the first half of the inductor (other terminal open) you get 10�H. You now measure the whole inductor and get 30�H. We can calculate that M=5�H.

Now forming a T equivalent of the inductor with one half shorted, L=10+5+(5//(10+5))=18.75�H. Notably, the current in the s/c is 3.75/15=25% of the current in the other section, so losses are about 6% of that in the other section... not usually a big issue.

That is, if I got the maths right on the fly!

Now, real inductors have some distributed capacitance which changes this as you approach the inductor's self resonance frequency.

This works ok because mutual inductance is lowish. Increase k by introducing a magnetic core material for instance, and the situation changes.

You might see the technique applied to powdered iron core inductors. Not necessarily a good idea, but it 'works' for some because they are low permeability powders and flux leakage is high (ie k is not nearly 1).

Owen

EM waves are the torsional vibrations in a solid dielectric. In solids are
the strains. Tiny flows.

> There may be some
analogous phenomena in plasma where you can get non-linear effects but
they would not propagate at c, they would be at some much smaller
velocity.

The vector calculus describe only movements.
Ancient people describesd the planet movements. But the planet were
described more later.

The same is with the radio waves. They are still not described physically.
In the description must be words electrons and voltage.

>Already answered earlier in this thread. For HF frequencies, the horizontal movement of the electrons is minuscule and they can be considered to be oscillating in place.

Waves are described in the two method: " More generally, the Stokes drift velocity is the difference between the average Lagrangian flow velocity of a fluid parcel, and the average Eulerian flow velocity of the fluid at a fixed position. This nonlinear phenomenon is named after George Gabriel Stokes, who derived expressions for this drift in his 1847 study of water waves."

> It is the photons that move at the speed of light.

Photons are the math joke.
Electric waves in a medium made of electrons move at the speed of light.

Light is not coherent. It is "produced" in the packets (photons). But the
radio waves and the radiation from the "free electron laser" are coherent.
When the photons start and when finish?

Not really... that used to be an explanation, because for conveniently sized coils, the length of the wire on the secondary is pretty close to a 1/4 free space wavelength at the resonant frequency. However, you can build tesla coils that deviate pretty strongly from that, and they still work well, indicating that the 1/4wavelength (or slow wave transmission line) model isn't all that hot.

The current/voltage distribution along the secondary is pretty close to linear, especially if you have a decent sized topload.

It's resonant, but not 1/4 wavelength. You can model a tesla coil's behavior to within about 5% using a simple lumped LC model. The secondary is a lumped L and the self C of the inductor plus the C of the "topload".

There's some pretty rigorous analysis out there of tesla coils these
days. Paul Nicholson's analysis is probably one of the best
http://abelian.org/tssp/

and has been confirmed by measurement.

Antonio C.M. de Queiroz has some elegant analytic models of coupled
resonators which adequately describe most tesla coil configurations
(including magnifiers) and more to the point, his analysis predicted
some new ways to operate a coil, which were proven in practice by some
experimenters. (that's sort of the proof in the pudding of theory.. it
predicts some behavior that hasn't been seen before, and when you look
for it, you find it)
http://www.coe.ufrj.br/~acmq/tesla/magnifier.html

There are some very nice finite element codes out there for Tesla coils,
as well. JavaTC is based on one of them
http://www.classictesla.com/java/javatc.html

But, isn't that conductive sleeve itself a shorted turn? It's
conductive, coaxial with the rest of the inductor above the sleeve, so
the magnetic field certainly passes through it.

I think the real answer is that everything is a tradeoff.

One could look at one of the standard equations for solenoid inductance (e.g. Wheeler's) and get a feel for it.   The ideal fully coupled multi turn solenoid would have inductance proportional to Nturn^2.

Wheeler (for inches) is: L (uH) = r^2 * n^2 / (9 * r + 10 * l)
so there's the n^2 term on the top, but there's also the 10*length term on the bottom.
For 2" diameter, 5 turns/inch, I calculated Wheeler L and for comparison Length^2/6 (so that the number would be comparable at a length of around 12")

length	turns	Wheeler L	uH/inch	Length^2
2	10	3.45	1.7241	0.67
4	20	8.16	2.0408	2.67
6	30	13.04	2.1739	6.00
8	40	17.98	2.2472	10.67
10	50	22.94	2.2936	16.67
12	60	27.91	2.3256	24.00
14	70	32.89	2.3490	32.67
16	80	37.87	2.3669	42.67
18	90	42.86	2.3810	54.00
20	100	47.85	2.3923	66.67
22	110	52.84	2.4017	80.67
24	120	57.83	2.4096	96.00
26	130	62.83	2.4164	112.67
28	140	67.82	2.4221	130.67
30	150	72.82	2.4272	150.00

You can see that for this kind of coil, the coupling from turn to turn must be pretty low.. The L looks closer to a linear function of length than to the square of turns. If it were perfectly linear, it would be as if there is NO turn to turn coupling, and is just a series combination of single turn uncoupled inductors. If you look at the uH/inch column you can see that once you get into the 10 inches long and up range, it *is* almost completely linear.

Owen <noone@no.where> wrote in news:vtKuo.256$tk4.180
@viwinnwfe02.internal.bigpond.com:

Well, I didn't get the maths right, there was a sign error in the formula below. Here is what it should have read.

Suppose you had an air cored inductor, that when you measure the inductance of the first half of the inductor (other terminal open) you get 10�H. You now measure the whole inductor and get 30�H. We can calculate that M=5�H.

Now forming a T equivalent of the inductor with one half shorted, L=10-5+(5//(10-5))=7.5�H. Notably, the current in the s/c is 50% of the current in the other section, so losses are about 25% of that in the other section... not usually a big issue.

Of course, the situation depends on the tapping point, and is much worse when you short just one turn... but we don't usually do that. The example has a fairly high coupling factor k (for an air cored coil), and losses are lower for lower k.

I am working on a note that expands on this.

Owen

the waves are photons, or the photons are waves, either way they move
at the speed of light, the electrons do not move at the speed of light.

well, if its not the perfect solution then the problem is not
completely solved... so there must be a better solution to really
solve the problem.

How can a model that presumes faster than light speeds yield a valid outcome? Drs. Corum seem to disagree with you. Here's what I have been quoting:

http://hamwaves.com/antennas/inductance/corum.pdf

Drs. Corum seem to debunk the lumped LC model. They also once had some class notes titled: "Tesla Coils and the Failure of Lumped-Element Circuit Theory", but I can't locate it on the web.

For an average air-core coil, the delay through the coil seems to be in the ballpark of half of the coil wire stretched into a straight line, i.e. the VF of the coil is about double what is the VF of the straight wire used to wind the coil. The turn to turn coupling exists but turn to far away turn coupling is very low.

This seems to be the most accurate inductance calculator that I have seen and includes the characteristic impedance and axial propagation factor.

The problem of transmission line losses can be solved with a perfect
lossless transmission line. Have you seen such or does reality force
us to settle for a reasonable non-perfect solution?

one could simply slit the tube (and finger stock at top). Consider that
the lower tube is serving two purposes: mechanical support and a movable
contact on the inductor.

Changed the topic.. and really, this isn't r.r.a.a territory any more.. Feel free to send me an email directly.

This has been thrashed through pretty thoroughly on the Tesla Coil Mailing List (TCML, http://www.pupman.com/) and I'd refer interested parties to the list archives, or, to the works by Paul Nicholson.

I've had some nice discussions with Corum the younger, but, their model makes life harder than it needs to be. Occam and all that.

At TC resonant frequencies (100kHz), the "light time delay" from top to bottom of a 3 foot high coil is pretty small. I don't know about faster than light, but at 100kHz, for an object that's a meter or two in size, assuming simultaneity isn't a big stretch.

(for the propagation of the spark, though, and the current flow in the top load, yes, the speed of light matters, and in fact, the speed at which the charge can get off the top load and into the spark channel is probably one of the bigger factors affecting maximum spark length.)

People have also put current and voltage probes at the top and bottom of the secondary coil (with fiber optic connections etc.).

Getting to the "transmission line" or "slow wave structure" aspects..

You've got an inductor with a lot of stray distributed capacitance. Indeed, that's exactly what a transmission line can be modeled as (distributed series L and shunt C). And with an arbitrarily complex nonlinear distribution of L and C, you can make a transmission line that acts like a lumped L and C of the appropriate values.

So, the question really is, do you want the simple model or the complex one. If the goal is to design better tesla coils, and the simple model gets you to fractions of a percent in terms of agreement between experiment and theory, why use the more complex model. It doesn't lead to any better understanding of how it works, either.

Now, if you want to talk about modeling the spark channel as a time varying lossy transmission line, that's something more interesting, and it DOES have value in terms of understanding/predicting the behavior. For that, I'd point readers to "Spark Discharge" by Bazelyan and Raizer, which is one of the best works in the field, and a fascinating read (and, as well, they have that cool 150 meter+ spark picture from a really, really big Marx generator, 1.2 MJ or more, in Siberia)

One thing I'm wondering. In your world, how does the energy jump from
electron to electron? And try to make some sort of sense for once. Please.

An EBAY picture of a Swan antenna c. 1960s was part of a thread. The patent number seen in the picture was below resolution. A search found what I think is the patent. It is only 7 pages long. U.S. Patent 2,961,657 Nov. 22, 1960.
Here are the classification numbers: 343/714 ; 336/150; 343/722; 343/745; 343/900; 343/906; 455/121; 455/92

Class 343 is the class for antennas.

You can go to this URL and enter patent number:
http://patft.uspto.gov/netahtml/PTO/srchnum.htm

YOU want backup data?? talk about the pot calling the kettle black,
where is the backup data for your levitating neutrinos?

Just a note ...
The signal that will make a switching diode go nonlinear will be Strong
signals (mostly AM/FM/TV) that are not even in the desired band. Several
receiver manufacturers even place a 20db BCB BP filters as the first
thing after the antenna connection and before the attn circuit (also
diode controlled)to prevent these signals from even reaching the first
BPF diode switching network. A bad thing for people interested in BCB-DX.

I think relays in the front end of any RX is a good thing. Relay
reliability has improved allot in the last 30 years too so longevity
should not be an issue in a receiver.

Excuse me, Bob, but no where in the description do they mention reed relays. I really doubt they are using reed relays because of the open capacitance of the contacts, plus, reed relays often stick shut because of fatigue, static electricity, and if left closed for a long time, metal migration will stick them closed.

Bet they are using regular relays, but in miniature form.

Paul

Bob,

you made an easy question and a difficult (for me) question.

The easy question.

> Haven't semiconductor switches, caught up with reed relays for this
> application by now, or do they "still" provide a lower "on" resistance, etc. ?

The problem of using diode-based switches is not in their higher "on" resistance, but in the fact that, even if strongly forward biased, they do not behave linearly, like a pure resistance. So, in presence of strong in-band or out-of-band signals, they can create intermodulation products. Increasing the diode forward biasing improves the situation, but the intermodulation performance of a mechanical contact anyway remains superior. Accordingly, some of the latest state-of-the-art transceivers (e.g. ICOM IC-7700) boast the use of mechanical switches instead of diode-based switches.

The difficult question.

> I am retired now, so haven't kept up withese things, or the state of the art
> nowadays, but are they still using electromechanical relays for
> front ends feeding a 16 bit A to D ?

I would re-formulate your question in this way: which is the point of avoiding the use of diodes OUTSIDE the A/D converter, if the A/D converter chip anyway includes switching diodes INSIDE it. This question is to be put to somebody who is familiar with the internal electrical design of A/D converter chips, and knows whether their internal structure is such to cause intermodulation products in presence of strong signals.

Measuring in at 0.1pF? the 1N914 (UHF switching diode) is easily 10 times this and more.

>plus, reed relays often stick shut

Ma Bell used them in the millions with 99.999% up-time.

>because of fatigue,

We are talking about a switch rated in the 100 Millions to Billions of operations.

>static electricity, and if left closed for a long
>time, metal migration will stick them closed.

That is true with issues compounding this, but as the receiver has its own spectral display, problems will be shown to you directly.

>Bet they are using regular relays, but in miniature form.

Which would suffer the same issues you offer above.

Reed relay usage design is not for the faint of heart, but when properly matched (an ugly word here) to the load, then they can provide service beyond your (and your children's) lifetime in this application.

In the oryginal Hertz dipole electrons jumps accros the big gap with the high frequency. Calculate the velocity.

>The key factor is the generation, by the oscillating electrons, of RF photons/fields/waves (traveling at the speed of light) .

Electrons do not need go-between. Electric waves are in substances and in the plasma (rare plasma in space).

>Where did this notion come from and what is its justification?

Electrons are expelled in the result of the voltage doubling in the end of
an antenna.

The transmitter create the pulsatin flow of electrons.
"Unsteady flow is present in man, machine and nature. The flow of blood in
arteries and capillaries in the human body is pulsatile- composed of a mean
flow superposed with an oscillating component. The tides that wash in and
out of rivers, harbors and estuaries are unsteady flows with very long
periods of oscillation. Many engineering devices employ pulsatile and
oscillating flow. Pulsating flow is defined here as a periodic flow with a
net displacement of fluid over each flow cycle. Oscillating flow is defined
as a periodic flow with a zero mean over each cycle."

"a periodic flow with a net displacement of fluid over each flow cycle"
needs a tank of electrons. It has many names: ground, counterpoise, radials
and chassis.
S*

than your levitating neutrinos. He thinks that its the actual
electrons that jump off the antenna and flow to the receivers.
Now ain't that a gas?

It seems that you do not know too much about the pulsatile and oscillating
flow.
"Unsteady flow is present in man, machine and nature. The flow of blood in
arteries and capillaries in the human body is pulsatile- composed of a mean
flow superposed with an oscillating component. The tides that wash in and
out of rivers, harbors and estuaries are unsteady flows with very long
periods of oscillation. Many engineering devices employ pulsatile and
oscillating flow. Pulsating flow is defined here as a periodic flow with a
net displacement of fluid over each flow cycle. Oscillating flow is defined
as a periodic flow with a zero mean over each cycle." From:

Hi All,

Thanks for all the info.
I've learned a lot, as usual, from the replies.
Thanks for taking the time; appreciate it.

Regards,
Bob (outside of Boston)

BTW: know of anyone who might be interested in a Yaesu FRG 7700 ?
       if so, please contact via: rgsroseX@comcast.net (remove the X)

great laugh isn't he art... you two should collaborate on a grand new
theory of em particulate flow, between your magical levitating
diamagnetic solar neutrinos that we are all drowning in and his
'pulsatile' electron flow maybe you could come up with something that
has even more humor potential!

Look at "Simplest Crystal Radi" in:
http://hackingwithgum.com/2009/06/08/how-crystal-radios-really-work/

There is the antenna, diode and ground. Is there the "pulsatile electron flow "?

If the transmitter produces the AC current and at the end of the antenna the voltage is doubled and the field emission take place is there the "pulsatile electron flow "?

In radials no voltage doubling so the field emissions take place only in one end.

Is it too dificult for you. You are an engineer.

how does the electron know if it is at the end of an antenna wire or
the end of a radial wire?

The challenge is to read the material and lose the stuff that is just plain wrong. When you find content that is wrong, it damages the credibility of the whole paper.

To demonstrate how poorly common mode current is understand, the following is a quote from MFJ's web site page describing their MFJ-835 twin needle "RF IN-LINE CURRENT METER, BAL.LINE, 1-30MHZ, 3AMP":

"How do you detect imbalance in open-wire or ladder line? By measuring and comparing each feedline wire current -- your feedline is balanced if the currents are equal."

Well, the line is balanced if the currents are equal in magnitude and opposite in phase (ie 180� out of phase). The MFJ-835 compares ONLY the magnitude, and it is true that if there is zero common mode current, a properly calibrated MFJ-835 will indicate balance, but it is NOT true that if the MFJ-835 indicates balance (equal magnitudes) that there is necessarily zero common mode current.

You will find articles on the net where authors have expounded the perfection of their station using the MFJ-835 as proof of zero common mode current, some even explaining how they continuously monitor balance (apparently at a fixed point in the line). The instrument is not suited to the job, and their results are flawed. The articles would make a good read if they weren't flawed.

Owen

The first sensible question.

"Radials and Counterpoises have two basic purposes:
1. To improve the RF ground conductivity for the ground current return path. Unless you live in a salt-water swamp, your ground conductivity makes a very poor path for the return of ground currents. This increases the ground losses and reduces the efficiency of an antenna that needs a good RF ground.

E. More radial wires are generally better. As the number gets larger, they improve the RF Ground less and less, to the point where there is no difference when adding one more radial to a system that already has 120 installed. Minimum systems of as few as 4 wires can provide an acceptable ground and increase the antenna's efficiency by a significant amount. Generally, 6-8 radials is the minimum that should be used." From: http://www.sgcworld.com/radialstechnote.html

As you see in the radials are many ends. There is the lower voltage and almost no radiation (electron loss). Radial work like the receiver antena (caught electrons from air)

Without the radials your stations can work only in a "salt-water swamp".

yes, but how does the electron in a single radial know it is at the
end of a radial and not double as opposed to the electron at the end
of an antenna that does double??

In each end the voltage has tendency to be doubled (standing wave). If you
have radials and the LED you can measure the voltage. It will be lower in 10
radials than in 6.
```

>as opposed to the electron at the end
of an antenna that does double??

You know what to do to have low VSWR. Low VSWR means that the voltage is so high that the intensive emission of electrons take place.

At higher voltage the emission or sparks make low VSWR.

oh, so the swr changes with transmitter power?  that is an observable
prediction that is obviously false... go back to square 1 and start
your theory over again.

If you believe ANYTHING that was published by SGC, you need to go back
to school and relearn everything you ever thought you knew about RF
Antenna Systems. There is a reason Don Stoner, left the company decades
ago, and PeeAir couldn't design his way out of a Wet Paper Bag.

Yes.

I think the write up on K1TTT's site will satisfy my curiousity and
find its way into my Permanent Reference File...
I still need a little more time.

BTW, I think my next lesson will be to understand Hairpin Matching. I
plan to start with the page on your website. If I get stuck I will
bring it back here!

So many fun things to learn, so little time!

John Ferrell W8CCW

We are discussing on the pulsatile flows of electrons and emission of them
from antenna end at transmitting.
At receiving the pulsative flow is in the oppsite direction.
Do you agree?

Yeah, have heard that described before ... medical marijuana has gotten
a lot more potent, huh?

Regards,
JS

Existence of the standing waves was shown by Oliver Lodge. They are in each
wire.

your theory over again.

Here no new theory. Pulsative flow and the field emission are very old.

Is the pulsative flow of electrons in antennas?

John Ferrell <jferrell13@triad.rr.com> wrote in
news:p2t3b697j43kj0qoj7jk43tn7im48dj44t@4ax.com:

> BTW, I think my next lesson will be to understand Hairpin Matching. I
> plan to start with the page on your website.

My page shows how to do it more thay why it works.

If you are interested in why it works, consider an L network to transform
a 20+j0 ohm antenna up to 50+j0. Think of a hi-pass configuration (series
C, shunt L), and find values for C and L. Understanding the L match is

essential to truly understanding the hairpin or beta match.

When you have worked that out, you will realise that you can create the series capacitive reactance by shortening the antenna (DE) a little. Yes, that also changes feedpoint R, but only very slowly compared to X.

The inductive reactance could be supplied by a coil, but at VHF it is more practical to use a s/c stub (which is the hairpin).

Back to how rather than why, if you use 4NEC2 to model antennas, it displays a parallel equivalent of the feedpoint impedance. If you shorten the antenna so that the parallel equivalent is 50 ohms // -X (Y=1/50 +j/X), then the hairpin has to supply X (B=-j/X) to cancel the -X (B=j/X).

Another application of the same concept is to shorten a loaded 80m mobile whip (which has low feedpoint R) so that the parallel equivalent is 50 ohms // -X, and shunt it with an inductor of reactance X to cancel -X.

Owen

no, the flow of electrons stays in the antenna and is sinusoidal...
they do not jump off the antenna.

I'm a pretty green in this area so I thought I would ask the enthusiasts:

I want to set up a wireless video link between my house and a construction site 1000 feet away. The area between is heavily wooded and hilly. I want to use a regular non-IP analog CCTV camera with 520 TV lines of
resolution. A 2.4GHz transmitter/receiver pair of 2 watts is my guess as to the link I will need. I will probably try powering my camera with a car battery.

What bothers me is that I've searched eBay up and down and cannot find a setup like this that uses anything more than a 420 TVL camera (and usually eBay has everything).

My questions are:

#1 Are my selections of frequency and power feasible? What would the advantages of the 1.2GHz or 5.8GHz bands be?

#2 Am I bumping up into some bandwidth limit with a 520 TVL camera? How come I am not finding any higher-resolution long-distance offerings?

Thanks.

In a cristal radio is the diode. The electrons flow from the antenna to
ground. Where they come from?

>they do not jump off the antenna.

They must do it in the transmitting antenna.
They are members of "pulsatile- composed of a mean
flow superposed with an oscillating component".

In reality no "sinusoidal...". The forward motion is always stronger than
the back.

give me a number. if i transmit 1kw on 14mhz how much dc current must
my transmitter be supplying in addition to the 1kw ac sinusoid that my
meter measures??

```

"... for a copper wire of radius 1 mm carrying a steady current of 10
amps, the (electron) drift velocity is only about 0.024 cm/sec". At
100 ns per RF cycle, the above electron moves back and forth about 10
nanometers, i.e. it doesn't "flow" anywhere except at DC.

At RF those electrons never make it from the antenna to ground and
instead essentially vibrate in place. The only thing that flows at the
speed of light is photons/fields/waves. The slow-moving vibrating
electron carriers form a bucket brigade for the fast moving photonic
energy. That fact of physics wasn't fully understood until the field
of quantum physics matured. EM fields and waves turned out to be
particles that are photonic in nature.

no whirls... the mathematical operator is called curl, but it does not
relate to the often pictured whirl or vortex.

I like it when there is mutual agreement.  Damn man, you aren't worth
the "paper" you write on ... I just love watching you go about it though
... keep up the good work.  <wink>

You are the best lesson in getting BS to float which I have ever
witnessed.  Seen some good ones, but I will admit, you are top of class!

Carry on, stiff upper lip, all that ...

Regards,
JS

http://borderinvasionpics.com/

Amateurs have had a long standing of being "American Pie", of being of the backbone of America. I know a lot of us where Boy Scouts, Girls Scouts, had a great respect for the American flag, God, country, family, etc.

I think we should take our radios, our antennas, and any other items which we can support our country, our family, our friends, and our fellow American citizens with ... what say you?

I think lines are being drawn in the sand ... I think we need to decide what sides we stand on, don't you?

And, I am sorry, to go off topic ... please accept my apologies.

Regards,
JS

Totally over the head?   Don't worry about it. What I wrote is only for
those who catch on. Don't worry though, the good Lord created such men
as to take care of you and never lose a stride! The design is
incredible and beautiful!

I have a Realistic DX-160 0.15-30Mhz Solid State Communications Receiver for which I want to build or obtain an antenna.

I can buy 500' of 14awg twisted strand insulated copper wire from Lowes for $40. Then what? I have two trees about 200' apart I could get the ladder and string the wire. Would that work?

I used to have a dipole antenna but it never seemed to make any difference. What component is in the nodes, anyway? A capacitor? A resistor?

In the meantime while I try and figure it out, I'm working on acquiring an 8' ground rod. Plus grounding the coaxial.

Is this radio even worth an antenna?

What about a vertical mast antenna? I don't need to transmit, just receive. How good do those work?

Is a wire antenna best strung E-W or N-S? I want Europe, not Spanish.

Apparently the end of the wire can act as a node to a wave 2 or 3 times as long as the wire. The length of the wire can divide into waves 1/2, 1/3, 1/4 etc. the length of the wire.

http://mypeoplepc.com/members/jon8338/math/id39.html

All I know has taught me I know nothing. Jon

The math is for the geometrcal description.

In Maxwell hypothesis are the molecullar vortices. The line of force rotate. Around the wire are the rings like the Helmholtz smoke rings. The line of force can rotate continously or oscillate. Nothing flow along the line of force. Maxwell did this model for the transverse waves. They are in solids and the math is used for the torsional vibrations.

Next Heaviside did more simple math for the TEM. It is tought as EM. But I dont understand it.

  This is a political problem, once the people convince the politicians this
is our country and we deserve, and desire to protect our boarder it will be
done in months.
  I think with all the violence spilling over, it could finally happen as it
should have 20 yrs ago.

You will probably receive lots of suggestions about your antenna. My comments are:

1. Longer is not better. Once an antenna becomes too long, it becomes more directional (in odd ways) and may have more tendenacy to overload the receiver. On the normal shortwave bands, receiver sensitivity is not the issue (assuming a reasonably practical receiver); the signal-to-noise ratio is the key element. A longer antenna can increase the signal but it usually also increases the noise to the same degree and this does not accomplish anything (except possibly overload the receiver).
2. A preselector can help prevent overload and may be a reasonable idea on a less expensive receiver. (But it is not necessary; try working without it.)
3. A vertical or horizontal antenna (or a combination) can work. A horizontal antenna may be less prone to "static" in your area.
4. Does the receiver have two antenna input terminals, with neither "grounded" to the chassis? If so, a dipole might be appropriate. More likely, it has a single terminal possibly with a second terminal optionally "grounded". In this case, a single wire to the antenna might be better. (The "feedline" to the antenna is part of the antenna also; try to keep it away from electrically noisy things.)
5. With a single wire antenna, try the receiver with and without a "ground" connection. It will probably be better with the "ground". You are unlikely to need a ground stake. Try connecting to the "third pin" (ground) of your electrical socket. Or, try two or three wires of different lengths (15 - 25 feet) laying on the ground (or under a carpet, etc). For receiving only, you can try many different things --- there is no "right" answer.
6. For listening on typical shortwave bands, an outside antenna wire perhaps 35-40 feet long should be sufficient. For what you describe, the compass orientation will not matter much. If possible, have the antenna up at least 30 feet and a little away from the house.
7. You did not ask about a feedline. For a single wire you could use coax. What might be better is twin line with the antenna end of one side of the feedline connected to nothing. The receiver end of this "nothing side" would be connected to the ground terminal of the receiver.

All my suggestions will be shot down on various technical points, but they may be reasonable for getting started.

Possibly the most important thing is to start understanding shortwave propagation. What times are best to listen for Europe on which shortwave bands? There are no definite rules here; the condition of the ionosphere varies from day to day and hour to hour.

Bill

You would be better off using 900 MHz, as the penetration thru trees
and terrain is better than at higher frequencies.
eyespyvideo.com has all the necessary components, including
transmitter, receiver, antennas, cables, camera, etc. They have
cameras with the resolution you desire. Use the highest gain antennas
available at each end.

Accch! Look what happens when I take a weekend off!

Okay now. I have the N3LI legal department working overtime now.

I am the person who invented the particles leaving the antenna theory. Not Art, in fact I declare prior Art, or even prior to Art.

Ive posted it before but probably before you joined the group, so here goes.....

The process of electromagnetic communications is all based upon tiny little turds that reside on your antenna. Very small turds they are, yet very powerful.

While transmitting, the little turds jump off the antenna, fly into the atmosphere or aether, and then eventually land on a receiver's antenna, completing the circuit.

This is why it is important to transmit every so often, so that your antenna does not gain too much weight. During solar maximum, inactive Hams often have their crappy antennas fall down.

Near the ocean the situation is worse, ya gotta transmit even more often, lest ye be shoveling s**t against the tide.

And it is a well known fact that antennas that are used more for transmitting take on a much higher polish, because there are less little turds, and everyone knows you cant polish a.... oh never mind.

Anyhow, despite some twisted language, it is obvious that these particles are a mer attempt to subvert the original and correct theory.

I have problem with the Faraday effect:
http://www.teachspin.com/instruments/faraday/index.shtml

"Although Michael Faraday discovered this effect in 1845, it wasn't modeled quantum mechanically until the 1960's. These theoretical calculations are too sophisticated for the undergraduate student, but an excellent simplified QM model is carefully presented in David Van Baak's AJP paper. (D.A. Van Baak, Resonant Faraday Rotation as a Probe of Atomic Dispersion, Am. J. Phys.64 (6) June 1996)"

In Maxwell's model inside of the solenoid are rotating wortices and they rotate the plane of polarization.

In Heaviside's model inside of the solenoid is a flux. Do you know (understand) how the flux can rotate something?
S*

you don't understand that the faraday effect relies on a material to do the rotation. the magnetic field itself does not cause the rotation it only aligns the molecules such that the polarization of the light is affected. you could just as well ask how can your hand rotate something when you turn a polarization filter or piece of feldspar with your fingers. if the material is not present the light does not rotate, and there are no vortices.

I can't see that it makes much difference, but is there any deference which
way the coax is connected to a J pole antenna. Is it better to have the
centre of the coax connected to the main element or the stub?
I notice that most if not all J pole designs on the net have the centre of
the coax connected to the main element, however when I refer to a 1977 ARRL
antenna book it has it connected the other way.

Is there any difference?

Peter

It is doubtful that one is better than the other, though the various
proponents are usually adamant that there is only one 'correct' way.

A better method is to feed the coax inside the tube at the centre /
bottom of the U section, and have it emerge at the feedpoint where you
bond the shield to tube at the emergence, and take the centre conductor
directly to the other side and connect it. Not as adjustable, but this
method incorporates a balun.

You can get nearly the same effect by strapping the coax to the outside
of the tube and bonding the shield at the bottom of the U section (as
well as at the 'feed point' of course)... but no one seems to do it. Not
surprising, as it is a measure to reduce common mode current which most J
pole devotees pretend does not exist.

Owen

do the rotation. the magnetic field itself does not cause the
rotation it only aligns the molecules such that the polarization of
the light is affected. you could just as well ask how can your hand
rotate something when you turn a polarization filter or piece of
feldspar with your fingers. if the material is not present the light
does not rotate, and there are no vortices.

In Maxwell's model: "In Maxwell's 1861 paper 'On Physical Lines of Force',
magnetic field strength H was directly equated with pure vorticity (spin),
whereas B was a weighted vorticity that was weighted for the density of the
vortex sea. Maxwell considered magnetic permeability ? to be a measure of
the density of the vortex sea. "

whatever was written in 1861 was either proved wrong or at least
incomplete. you are 140 years out of date, first year college physics
and electrical engineering fields courses teach stuff that would have
totally amazed maxwell and friends in their simplicity and accuracy.

Owen
Every set of instructions I found when I was building my collinear J-pole included a BalUn in the design.   Some of the users of these antennas are not fanatics but simply find it easier to use six turns of coax as the the BalUn. And as to why it is simply easier to apply. Since I am getting to the place were I don't like the inelegance of the coax BalUn I will soon be changing over to a ferrite bead BalUn for the sake of it's lesser ice collecting properties, it's improved appearance, and smaller visual profile. Not everyone believes that the antenna that they are using is magic. Many have other reasons for not doing it in a particular way. Other than the No BalUn voodoo are there other reasons that you don't like J-poles?

It is not that I "don't like J-Poles", but that they have certain characteristics that should be considered in their design and implementation.

They are an 'end fed' antenna, and there is necessarily some common mode current excited on the feed line / supporting mast structure. A balun helps to reduce that, and I described an integrated balun that is an elegant construction, though a further ferrite current mode choke would be of benefit.

The plumber's delight construction which is often hailed as an advantage is actually a frustration when trying to reduce common mode current.

Though the J-Pole is often promoted as a easy thing to implement, they figure disproportionately in online forums with questions like "I adjusted my SWR real good in the shop, and when I raise the thing, the SWR changes". The common sensitivity of measured SWR to antenna position and line placement is a sure sign of high common mode current.

The common mode current doesn't necessarily stop them working, but it does frustrate setup, a trap for the inexperienced.

BTW, J-Poles are not popular commercially in this country, I cannot recall ever seeing a commercial J-Pole for non-amateur use. Perhaps there is a message there about convenience and predictability for the installers.

If a J-Pole suits your requirement, go for it. They warrant an effective common mode choke, if for no other reason than to make VSWR less dependent on the layout below the feed point.

Owen

The big question I have always had regarding the balun was are we
reducing performance by eliminating feedline radiation? For a lot of
antennas, that may be a big part of the antenna system.

For shorter wavelengths, like 2m, feedline radiation is bad news for
the radiation take-off-angle. It essentially makes the antenna a lot

longer than 5/8WL, i.e. end-fire, sending most of the radiation up at
a high take-off-angle.

Claiming feed line contribution to radiation as a performance factor is usually a specious claim, and more likely to be made by someone with a commercial imperative than a genuine interest in radiation performance. You know, if you can't solve a problem characteristic, call it out as a feature.

In this case, feed line radiation would usually skew the pattern upwards, not necessarily a desirable feature, probably not desirable in most situations.

I don't disagree, but certain antennas - the EH antenna comes to mind, which resemble a tuned circuit on a stick. Get rid of the feed line radiation, and you almost get rid of the whole antenna. But like you say, its a "feature".

It's also not good practice.

> In this case, feed line radiation would usually skew the pattern upwards,

Not too desirable. Thanks for the clarification. Mine was a general sort of response, not limited to this antenna.

I have an application, as part of a bugcatcher antenna, where I would like to run a number of wires, maybe 6, to the coil as connections to taps, and run them at an approximate 90 degree angle to the coil.

Will these wires have much of an effect? I'm going to try it regardless, but it might be good to avoid something that is obvious to the more seasoned Ops in here.

why don't you go buy a modern physics or electromagnetics text,
something printed in the last 25-30 years and get up to date

Hi Mike:

I would try it. I remember vaguely of a commercial mobile antenna that did just that. If I remember correctly they mounted the switch on a bracket on the coil to keep the connecting wires as short as possible. It will be hard to keep the bugs out though.

John W3JXP

Many years ago, one of the 75m CA shootout hams did this very thing
and it worked well.

Or get pretty close to up to date with "QED", by Feynman.

"So now, I present to you the three basic actions, from which all the phenomena of light and electrons arise:

-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

I know what is in books. I am interesting in the reality. Now I know that in
a cristal radio the electrons flow from an antenna to ground because there
is the diode.

So in a transmmiter station the electrons must flow (pulsatile flow combined
with the oscillations) in the opposite direction. Could you detect it?

You are confusing the impulse (photonic) flow of EM energy, with the electron carriers which move hardly at all at HF. Hint: Electrons cannot move at the speed of light yet we know that EM energy moves at the speed of light.

In a somewhat similar manner, the impulse energy in a tsunami wave travels a lot faster than the water molecule carriers which move mostly up and down. Tsunami waves are hardly noticeable in the open ocean.

the reality is what is described in the current texts used in
colleges.  and no, you can not measure a net flow of electrons in a
```

```
transmitting antenna.

After the PAQSO party,my loading coil was incredibly full of bugs.

I'm hoping that I can at least avoid the constant trips outside to
```

```
change taps on 75/80 meters. The antenna performs well, but that sharp
tuning can be an issue.

Good to hear. I've been really happy with the performance of the
antenna, but 80 meters was like a step aerobics class. Contesting just
has too many frequency changes.

>You are confusing the impulse (photonic) flow of EM energy, with the
electron carriers which move hardly at all at HF. Hint: Electrons
cannot move at the speed of light yet we know that EM energy moves at
the speed of light.

Air particles move at speed of sound. For this reason the speed of sound is temperature dependent.
The same must be with electrons. Do not confuse the mean velocity with the max. In air the mean speed is also close to zero.

>In a somewhat similar manner, the impulse energy in a tsunami wave
travels a lot faster than the water molecule carriers which move
mostly up and down.

Water molecules move mostly horizontally. See:
http://en.wikipedia.org/wiki/Stokes_drift

>Tsunami waves are hardly noticeable in the open
ocean.

Because tsunami is the simple flow.

So they should be taken from the ground, send in the ether, land on a
receiver's antenna and flow to ground, completing the circuit. Is it
possible to detect it?

If it's good enough for an antenna tuner (MFJ-949E) then it should be
good enough for a loading coil. After all, the same amount of power is
involved.

sure, put your antenna in a glass bottle, seal it in with good glue so
nothing can slip out that way... then transmit, the inside of the
bottle will instantly be covered with little turds so you won't be
able to see the antenna any more... case closed.

Most loaded antennas that are very short for the frequency will be sharp
tuning. If the tuning is very broad, it is usually an indication of a lossy
antenna system

Hi Mike,

Run those wires to what? What length wires?

>   Will these wires have much of an effect?

Sure. Will it matter? You (the reader who performs this aside from you, but including you) wouldn't necessarily know where the antenna would have resonated to begin with, and any change could hardly surprise you in that regard. Aside from issues of resonance, we would consider loss. As you are running them at 90 degrees (the ambiguity has me wondering, do they spoke into the coil, or out?), then you are seeking to avoid wire spacing issues that force Ohmic loss through proximity. Given that, loss would seem to be a non-starter. If the wires are long (again, the ambiguity of where they go), then they become part of the radiator, and as such would intercouple. As the entire construction is a wild card in resonance, this would not seem to be problematic anyway. On the other hand, it could diffuse control and present some odd tuning characteristics. This would only add to the lore and you might be able to call it the Beneficial Coslo Effect and we are blessed with the BCE 'Tenna (I won't use the full word, as doing that will depreciate the legendary value). As we all know, any new name inherits at least 6dB gain in performance.

 What percentage of water molecules are moving more horizontally than vertically for what percentage of the time? That percentage is certainly pretty small. Even for those normal steady-state waves, it appears that the vertical motion at the surface is still greater than the horizontal motion for at least half of the cycle. *Anywhere except at the very surface, the vertical motion is obviously greater than the horizontal motion*. But the subject was a transient tsunami wave where the horizontal motion is virtually non-existent because of inertia.
Thanks for the example that proves my point.

Borders aren't the problem, where are the secure borders in America anyway? Not that mulitibillion dollar fence between mexico and U.S., that has more holes than swiss cheese. And not the border between Canada and U.S. that is more micky mouse than any other country in the world. Only concerned about taxes.

So borders aren't the problem and the west really should increase its population by allowing more in to bring more manufacturing and jobs to the west. You will all want to protect your high paying jobs, however as Amateurs know the world got smaller and things have changed. Why doesn't the west change with the times?

The original poster here is just a thumper, with no economic knowledge, no biblical knowledge, but raises a good point, the west does need to remove its borders so the country's econonomy can rebound. We need cheaper labor in other words. The more people the more the price is reduced.

Initial idea is to run the separate wires as taps on the coil. I'm
intending to run them on the outside of the coil, probably separated

about an inch away. The wires would then go to a (insert whizbang gadget here that I'm still figuring out) which then switches taps as needed. I'll probably start with manual switching. There is also the matter of that tuning coil at the bottom of the antenna to ground, which varies between 8 turns of number 12 on a 1.5 inch diameter coil on 75/80 meters, to no coil at all on 20 meters, which is the highest frequency it will tune at.

The antenna itself is semi-standard bugcatcher, a four foot bottom section, followed by the six inch coil, (standard GLA systems) followed by another roughly foot and a half section, then a 16 inch Capacity hat, then a spring and topped off with a 102 inch whip. Taps at the present short out the remaining coil below themselves. The whole thing is mounted on the spare tire holder - the spare resides in the back of the vehicle while mobiling.

Needless to say, this thing is tall. There is a monofilament line attached to the top of the antenna with loops at various places, that I pull and hook around a convenient place in the interior. 50 pound test is what saves this antenna from trees, branches, etc. Since people can't see the line, the setup - which as you can imagine gets some stares to begin with - eyes bug out when it appears to be moving all by itself. But I digress.

Anyhow, I pretty much assumed that there might be some small tuning differences on the lower frequencies, but I was just making sure that I wasn't running the road to perfidy with any hidden "gotchyas" - like if a stinger goes too far into a loading coil - one of those things that might not be completely intuitive until after the fact.

Really sounds like you are reinventing the old Swan mobile antennas. I
have an almost new in the box, motor driven unit that has the
switching mechanism just like you are thinking about. The motor in the
bottom unit has a dial-cord wound around it's shaft. The other end of
the coil loop goes over a pulley and a sliding contact is attached to
the dial-cord.

Is this what you are envisioning?

Paul, KD7HB

Hi Mike,

A rare confab of actual antenna design details. No controversy. No wonder there are so few postings. Mike, on this cat walk of fashionable posing, you are a buzz-kill.

How long are those tap wires? In other words, is this manual switch sitting on your dashboard?

>There is also the matter of
>that tuning coil at the bottom of the antenna to ground, which varies
>between 8 turns of number 12 on a 1.5 inch diameter coil on 75/80

Why have a coil there at all?

>The antenna itself is semi-standard bugcatcher, a four foot bottom
>section, followed by the six inch coil, (standard GLA systems) followed
>by another roughly foot and a half section, then a 16 inch Capacity hat,
>then a spring and topped off with a 102 inch whip.

Uh-huh. So you have a "top" hat that is actually very close to the center? A center hat as I might be wont to describe it?

I've often thought (and probably modeled at some point in the last 20 years) about putting such "top" hats at regular intervals along a vertical radiator. Sort of like a bottle washing brush kind of design.

>Taps at the present
>short out the remaining coil below themselves.

Back when we had more designers writing here, instead of Xerox junkies and home-spun Platocrats, the discussion of shorted coils made them apoplectic where those turns became huge losses. This is different from the screwdriver approach which shields those turns.

>Anyhow, I pretty much assumed that there might be some small tuning
>differences on the lower frequencies,

Well, as I inferred, IFF you knew what frequency any unadorned (unchanged) original design was going to reside at; then I could well imagine it would shove that understanding under the bus. IFF, on the other hand, you have no idea (other than a general one of plus or minus one MHz) of where the initial state of tune was, then it probably wouldn't matter.

>but I was just making sure that I
>wasn't running the road to perfidy with any hidden "gotchyas" - like if

>might not be completely intuitive until after the fact.

But of course you will (I'm looking forward to those stories) -
otherwise you would have bought an antenna with a guarantee. In
regard to this last I have to tailor a quote from one of my favorite
authors, Walter Mosely:

"...you won't get to enjoy the honey,
if you worry the bees be stingin' you."

8^)

> How long are those tap wires? In other words, is this manual switch
> sitting on your dashboard?

The initial plan is to have something perhaps located on the lower mast
so that I can experiment with it. the final version will be eletrically
or electronically switched, (most likely electrically) the switching
taking place at the antenna - probably located on the lower mast.

>> There is also the matter of

>
> Why have a coil there at all?

It's sort of the butternut HF6V (and family) thing, I can tune the
thing, but unless I place a Matching coil there, the minimum SWR might
be around 2.5 to one or even higher, except where the antenna is
becoming a more normal length. In the end, it's no doubt to compensate
for the crazy low impedance on a short antenna.

>> The antenna itself is semi-standard bugcatcher, a four foot bottom

> center? A center hat as I might be wont to describe it?

Yup. I had looked at placing it higher, but that ended up defeating my
tie down idea, and those cap hats are kinda like wind dams - In the end
I wanted it attached to some sturdy part of the antenna.

>> Taps at the present
>> short out the remaining coil below themselves.

I'm wondering where the issue comes from. As I look at it, the shorting
is making the bottom part of the mast slightly longer. I have to imagine
that not shorting it would be worse. Dunno, though.

>> Anyhow, I pretty much assumed that there might be some small tuning

I'll end up knowing, my tap system so far is a modified clip that has a marked place on the coil. It works ver well, when very well is defined as stays on and sends to power where I want it.

What got me started was last weekend, out late at night in just about the most rural area in Pennsylvania, dragging out a stepstool to change 80 meter taps. New moon, and I forgot my flashlight. While the antenna "works" pretty well for the genre, needing a stepstool is just not that wonderful.

Here is an older Ebay listing that shows a Swan mobile antenna with
manually adjustable taps.

http://cgi.ebay.com/SWAN-Swantenna-45-Five-Band-MOBILE-ANTENNA-Selectable-/=
370422708798

When I lived in an apartment temporarily a few years ago I had a
similar situation. The back of the apartment and my bedroom window
faced a wooded area so I strung up about 50 or 60 ft of wire using a
long piece of PVC pipe to push it up into the trees. I used it with my
MFJ tuner and enjoyed a lot of SWL time. Yes the tuner helped compared
to the antenna terminated in a banana plug and pushed into the
connector on the back of my IC 729. Take notes on how you set up the
tuner for various frequencies

Hi Mike,

That, too, was part of the raging debate. I have long forgotten the particulars, but I will hazard their argument. That is, in these highly reactive designs there are large potentials and high currents. With those circulating currents (the usual province of these considerations are in the tuner) AND the proximity of a shorted turn, you have a transformer relationship feeding the loss of the small diameter wire and/or the resistive short (rarely do switches offer optimal solutions in the face of truly enormous currents).

Screwdriver designs pre-empt this through the coil being nested inside of the conductive cylinder - no transformer action, or at least so goes the argument.

Reggie entered into these issues with his own observations about coil length, diameter, winding pitch, and placement to summarize his optimal design. You may want to look into that insofar as your base loading goes.

I enjoy making my antennas also

But this 8bay hd antenna is pretty cheap. I see it for pick up at 69 dollars
in Toronto. Plus some taxes of course but looks like a pretty solid antenna
for that price. I cannot imagine how much time one would spend getting all
the parts then assembling. I think just too easy to buy today.

Good luck with the build.
I am going to buy two tomorrow, throw them on the tower and be done with it.

I am inclined to agree with you. I expect this to be my recomendation
for the folks around me who are looking for an antenna for HD.

However, there is this young fellow who is bent on building his own.
Given that he just might execute this project and then move on to more
antenna projects, I think I owe it to my early mentors to cultivate
his curiousity.

Perhaps acquiring this antenna and using it's performance as an
objective for diy models will fit well.

I am a Channel Master fan. I don't think you can beat their
price/perfomance in any of their products.

I have explored what you have said in an NEC4 model of a quarter wave monopole with three quarter wave radials at varying heights over 'average ground'. The results are summarised at http://www.vk1od.net/lost/Clip053a.png . The reference for the graph is the efficiency of the same antenna with 120 buried radials in the same soil type.

If the models are correct, laying just a few radials on or very close to the ground (eg the popular method of pinned into the turf) would appear to be a very poor option. The model indicates efficiency improves with a very small increase in height above the dirt, just 30mm is a 6dB improvement of lying on the dirt, just half a metre achieves 90% of the available efficiency.

Owen,

Based upon your findings above, have you thought of increasing the height
of your model to determine at what height would be necessary to equal the
same efficiency as your 120 radial reference?

I don't think it is a simple as that Danny. With sufficient height, the pattern changes significantly and so you cannot compare the antennas on efficiency alone.

It might seem intuitive that a ground plane a very long distance (say km) above earth would approach 100% efficiency, and we tend to assume that for VHF ground planes many wavelengths above ground, the model does not indicate that. At sufficient horizontal distance above flat earth, some rays must reflect off the ground and so warm to soil to some extent, no matter how high the antenna.

The study was more to answer the question whether elevated radials were effective, and how high they needed to achieve similar performance. The model suggests that just three radials at 2m height is about 1dB down on 120 buried radials, or about 90% of the efficiency or EIRP (since patterns are almost identical).

Thanks Owen for the Clip053a.png
The results are just amazing.

But I just cann't understand why the current in the radials, don't
induce a significant current in the earth, that ends as an important
lost power.

Dear John:   Well said.
Last year, a colleague (also a radio amateur) had his EE class design a UHF
(14-52) antenna using EZNEC, then construct the antenna, and then he took
the resulting antennas to an antenna range for testing (he had a grant to
cover the cost including cost of EZNEC).
The design of an antenna to cover not only 14-52, but also 7-13 is more of a
challenge.  In this area, we have one station in the 7-13 range.  I use a
Wineguard HD1080, which is a two bay with extensions on each fat dipole.  A
second colleague with an antenna that was in bad shape after 30 years, just
replaced the old antenna with an Antenna Craft HBU33 with a huge jump in
signal and significant reduction in wind load.
Channel Master is good too.  Much discussion exists - as has been observed -
about the 4228.

Obviously, it is improbable to have an eight bay antenna realize its
theoretical gain over the BW needed.  I would stop with four.

Is a Screw Driver antenna nothing more than an antenna tuner you mount
to a vehicle with a piece of wire attached to it?

The first screwdriver antenna was homebrewed using a cheap cordless
screwdriver to adjust match ...

But, a real screwdriver antenna is one you have to get out and adjust
with a screwdriver every time you go over a big bump ... or it rains ...
or a bit of corrosion happens ... <straight face>

Regards,
JS

I have the all the gear from a vintage Ham Shack for auction. Mostly vintage Drake gear. Really super clean and nice.

Drake L - 4 B Linear Amplifier + L-4 PS Power

Drake MN - 2000 Matching Network ~ Ham

Drake R-4C Ham Receiver

Drake T-4XC Transmitter ~ Ham

DRAKE FS4 SYNTHESIZER ~ Ham

Drake MS-4 Speaker + Drake AC-4 Power Supply

CDE Transmit Receive Direction Control ~ Ham

Shure model 444 Base Microphone Ham

Follow the link for photos and a full descriptions of each piece of gear....

http://members.ebay.com/ws/eBayISAPI.dll?ViewUserPage&userid=iam30

Thanks

The picture of the drake amp sure brings back memories from the 70's.
If I remember correctly, about 600 watts am was about all you expect
from the amp when using a sane drive and 1KW input. (something I rarely
did back then)

A solid amp, but was made obsolete with the high power mosfet amps
coming out in the 80's. The first homebrew 1KW amp I ran was ~85%
efficient, 850w am out on 1KW in ... and if you take filament power into
consideration, the drake was simply blown away by advancements in
efficiency ...

```
Still, an excellent collectors item and the one in the pics looks like
it was well taken care of ... however, I wonder about the state of the
3-500Z's ... they are getting expensive and in shorter supply, at least
around my area.

Sort of.

After you accept that as the objective the clean up involves:
Physical details ... rugged beyond belief, small enough to be
acceptable... maintainable...weatherproof... under daily hurricane
conditions... affordable materials

install issues... different vehicles require a lot of flexibility in
mounting.

I have a project underway where I expect to have a Homebrew T-Match tuner at the base of a vertical antenna at my QTH. I plan to drive the mechanics with three $10 electric screwdrivers. Locating the tuner at the antenna will allow the feed line to operate at a low SWR which will keep feed line losses to a minimum and rf out of the shack. Since the contraption will be in the garden shed most of the difficult aspects of a vehicle mounted screwdriver antenna will be out flanked.

If you sit down and plan it through I expect you will conclude that the only reasons that you might have to homebrew a vehicle mounted Home brew Screwdriver antenna is that you have excess time and materials or you think you can improve on the commercial offerings.

Sometimes my only real motivation is that I have to homebrew an item before I can fully appreciate the commercial offerings!

BTW, an SGC-237 tuner and a 28 foot whip will tune all of the HF ham bands automatically and fast! That set up will cost a lot more than a

commercial screwdriver but you can consider that as an ideal
arrangement and compromise your way back from there.

Good Luck,

John Ferrell W8CCW

The feedpoint impedance of a 28 foot whip on 3.8 MHz is ~5-j620 ohms
(according to EZNEC) which means considerable tuner/ground losses
(~9dB) =3D not ideal IMO, compared to a 1/4WL monopole. If one wants
reasonable performance on 80m, best to stick with not much less than
3/16WL =3D ~46'.

The Take-Off-Angle of a 28 foot whip on 28.4 MHz is ~43 degrees =3D not
ideal IMO, compared to a 5/8WL monopole. If one wants reasonable
performance on 10m, best to stick with not much more than 5/8WL =3D

~23'.

There's no single monopole length that is optimum from 3.5 MHz to 29 MHz. Just about the best compromise we can reach with an autotuner at the base, IMO, is the 46' monopole for 80m-20m operation or the 23' monopole for 40m-10m operation.

Which is why the whips that SGC sells (and others use) are typically two
monopoles in one.. I have fairly good luck with a 9ish foot CB whip with
about 25-30 feet of wire roughly spiraled up it. The precise length
isn't real critical, as long as you don't wind up with an anti-resonance
in a ham band making it hard to match.

Thank you Jim for the explanation. Sorry I wasn't more specific.
I was refering to the difference between receiving and transmiting gain.

I'll try to get a shot Helmut...

Well, I tried the 61 material ferrites, and it lowered the SWR
significantly. No matter where/how the cable comes off, it appears to
work best right behind the feed point. Only one of the large 1" ones
seems to be needed. I tried adding more, but it didn't really make a

difference. It's still not perfect, but it's way better than it was
before.

The gain effect is the same, but for a lot of radio applications, gain
is important on transmit, but less so on receive, where good back/side
performance (e.g. low gain in undesired directions) is important.

That is, my transmitter doesn't care about a strong interfering signal
from a different direction, but my receiver sure does.

Hi

I'm anticipating converting my coax fed, ninety foot long, folded terminated dipole to a ladder line fed folded dipole, without a terminating resister, fed using an Icom AH-4 antenna coupler. Am I correct in believing that the best ladder line to use for that purpose would be the 300 Ohm type to match the nominal impedance of the folded dipole itself.

Mostly, a TTFD would be used as a multiband antenna. If that remains the
case, the folded dipole option is probably not as good as an ordinary
centre fed dipole, and there is no special magic to the 300 ohm line.

Speaking of which, you may find the article
http://vk1od.net/transmissionline/300/davis.htm of interest, expecially if
you intend using it on 80m or below.

Owen

Antennas usually are made of aluminum as copper is somewhat heavier
and silver and gold is to expensive. Since lead is now banned in a lot
of places especially with solder you can now buy solder that is doped
with Bismuth !
Now you can't coat your elements with it but if you have a solder
bath you can run copper wire thru it. The bismuth is brittle
but with the underlying copper it is stiff enough to stick it on the
antenna elements. I am assuming that the applied current would travel
along the bismuth coating instead of the aluminum and therefore should
increase gain for antennas that use coupling methods such as the Yagi
tho bandwidth may well suffer some what.
What do you think?

What do I think? I think I'd rather have a platinum antenna! Sure, it would be a lot heavier than aluminum, or even copper. Sure, I'd have to keep it in a bank ... but, I'd still like it!

Regards,
JS

Lead free solder is still mostly tin.

You guys are just nuts to consider messing around with a device capable of emitting Orgone Radiation!

I mean, you may doom yourself to a life of having to use medical marijuana to alleviate the migraine headaches and pain! Not even getting into the heavy genetic damage which is likely to occur!

Regards,
JS

Is this a multiband application?
If you want to keep all the wires, I'd make it a fat dipole (rather than
folded).
Why not put the AH4 at the feedpoint and feed with Coax? The box *is* a
bit heavy, but it is weatherproof, and you could run the power/control
wires alongside your coax.

I am not sure whether you are considering coating the elements with solder, tin, or bismuth... but they *all* degrade the RF resistance of an aluminium element.

Nevertheless, hams are suckers for snake oil salesmen. Just look at the products sold for antenna wire, open wire feed line and whips... so you might have an opportunity there Art.

Owen

Hmmmm!
Isn't the idea to get current to flow on the surface
without the skin depth problem? For instance, when you make a Meander
antenna distributed loads are not existent as they cancel out. This
also means that skin depth is non existant as there is no magnetic
field. Thus there is nothing to prevent the current going beyond where
the skin depth is usually situated where it can continue on to flow on
the surface the path of least resistance.
Now the element resistance is of no concern as it is not now part of
the radiation circuit!   Instead of two resistances we only have the
one which pertains to radiation, the sole object of a radiator.
Capacitance and inductance does nothing to advance radiation, tho it
is quite useful to have in other areas of science so why fool with it?
Magnetism and polarization only comes into the picture after
propagation is initiated when particles/electrons are ejected with
helical spin and acceleration which generates various movements,
fields etc after the fact.
Remember, for both transmission and receive the only object that can
```

break up the parts of electrical and magnetic fields together with
time varying current is the Faraday cage, so it is useful to start
with the cage function to get a true story of radiation. A radiator is
only efficient when you can present a flow path for applied current
where the
source becomes totally resistive.
I threw Bismuth in since it is part and parcel of the superconductor
scenario. grin." Super" has many pleasant conoctations for a salesman
to use.

you see art, they just don't understand how the magical levitating
solar neutrinos will jump from the diamagnetic bismuth much more
efficiently than from aluminum... and they never will understand until
you can explain how my ferromagnetic vertical antennas that obviously
can't support a coating of your magical levitating solar neutrinos
could possibly work at all.

because the currents in the radials cancel out below them which reduces the current in the ground. as long as there are enough of them and relatively symmetric. look at a radial field from below, lay on the ground and look up at the radials all branching out from the center... now visualize the current in each one, note that they are all in phase, the current flows out from the middle to the ends all at the same time. now if you start adding up the vector representations of the fields from each little piece you will see that ideally they all cancel out. in the middle that is likely pretty good, but as you move out from the middle you get farther away from the radials on one side than the other so cancellation isn't as good, but the current is also lower so not as much gets coupled to the ground.

Ferromagnetic materials will work but the diamagnetic vectors get a
bit swamped in competition. Any good physics book will explain that
phenomina or alternatively look up wilkpedia.
Didn't you once state that physics was your major?
Your statements appears to put that as a matter of fiction. Why not
explain radiation from your point of view? You can have your posting
removed after a given time in case you embarrase yourself.  Tom where
did all these weirdoes come from ?

no, i'm an ee, not a scientist... my company wanted to change my title to scientist once, i told them only if i could put 'mad' in front of it and they let me keep the engineer title. I have to go with the writings of the masters as mr. b would put it, except i got with the final set of maxwell's equations as published in books like jackson and other contemporary writers... which, by the way, do explain that gauss'es law is a part of maxwell's equations and is a dynamic equation even without the explicit 't' in it.

Tom, you like many others, feel that your postings are like a private
E mail, but it is not. Your writings
and past postings are available for all to see and judge what sort of
person you are. You continually embarrase yourself. I invite all to
view your past postings to see what manner of man you really are.
As for the Peltier effect that you are referring to, it is you who
needs to check the facts as to who posted that. It certainly was not
I. But if you have the real facts then spit it out to show that you
know them and can prove it, until then you are spitting into the wind.
So Tom back to you. What are the "real" facts that you wish to point
to and be specific with respect to the connecting physics for
supporting data? You may have a open physics book at your side when

responding so you can read up on diamagnetic, levitation, neutrons etc since it is very clear that you were able to jump semesters at will leaving large holes in your educational standing which does not allow you to debate in a reasonable fashion.
OR
You can continue with verbal bullying without contribution or follow up discussion with other members of the group.

So what is your point exactly? Are you holding on to
radiation by "waves" instead of "particles" or what?
What is the specific relevant law of Gauss that you are referring to?
Show me specifically what Jackson states so I can get a handle on the
specific problem in question. I have no idea what is troubling you
whether it be levitation which you call "magical", "Neutrinos" which
occupy every cubic metre in the atmosphere on Earth. Or, the "double
slot" experiment which opposes a particular law of Gauss. Spit it out
specifically and I and the rest of the group can then discuss it. As
an aside, Gauss's work is in the form of cgs units which are not the

```
same as Maxwell's units so you have to be careful as how you explain
"this matches that" in your response when and if it comes up.
Regards
Art

With respect to the works of the Masters which one could include the
books by Jackson and others.
They all state that Gauss;'s law on MAGNETISM
was included in Maxwell's laws or equations on radiation. I know of no
text book that outlines the connection between ":statics" and the
equations of Maxwell. A debate was held on this forum on the
connection between statics and Maxwell which was held in denial by
all. After a year or so the statement was made that" the Jackson book
outlined the connection between Gauss and Maxwell" so the connection
of statics was wrongly connected to the Gaussian law on" magnetics"
and not his laws on "statics.".
The boundary laws of Maxwell which is the basis
of all of his equations are also those of statics which, when made
dynamic, are the one and the same equation arrived at by Maxwell . I

know of no mention in any book on radiation that equates as fact that classical physics mathematically supports the position of particles as the root of propagation which is in agreement with Einsteins laws on Relativity. Point being that mass is required for "acceleration of charge" as with particles./ electrons
and to my knowledge has not been stated as the Gaussian connection to Maxwell..... anywhere!
I would appreciate it if you or anybody can point to where I am in error and where your position can be determined as credible.
Regards
Art.

It's quite well known that the best antennas are built from zircon encrusted wire, which is trimmed using only zircon encrusted tweezers.
If you can look at the wire ends on a sunny day and can see noticeable tweezer glint, you know you have a world class antenna system worthy of the masters praise and endorsement.

WOW! Another one of those which you always wondered about, but were too ashamed to ask about. I just knew there were others like me who must have wondered about it. Now that you have just tossed it out like so much fact ... I realize I was silly not to have asked.

We are much better off for having had you share that with the group.

Many thanks,
JS :-)

The model results do not support the common Rules of Thumb (RoT) or
explanations that I have often seen on the subject of elevated radials.

The model suggests that as the 3 radial system is lowered, efficiency
(meaning total power radiated in the hemisphere divided by power input)
changes little until the radials are 100mm above ground, and the
efficiency drops quickly, more quickly as the height approaches zero.

I interpret that to mean that there is little elecric flux in the soil due to antenna currents for this configuration until the radials are very close to the soil, and then the loss effects grow very rapidly. I assume that the losses are mainly due to dielectric effects in normal soils, but that might be different if you had magnetic material in the soil.

Is this surprising? I think that if you wanted to make a device to warm soil by dielectric heating using RF, you wouldn't expect it to be very effective if the conductors weren't very close to the soil.

Using more radials reduces the losses.

If you can visualise the electric field flux in the case of the monopole over three radials, and compare it to a horizontal dipole, you may get an insight to why a low dipole is more effective at heating the soil.

Owen

> radiation by "waves" instead of "particles" or what?

In reality are the continuous flow and the oscillatory flow. Flow of the particles. The oscillatry flow is the wave.
In the ink printer works the oscillatory flow. In antennas and the space also.

>With respect to the works of the Masters which one could include the books by Jackson and others.
>They all state that Gauss;'s law on MAGNETISM
was included in Maxwell's laws or equations on radiation. I know of no text book that outlines the connection between ":statics" and the equations of Maxwell. A debate was held on this forum on the connection between statics and Maxwell which was held in denial by all. After a year or so the statement was made that" the Jackson book outlined the connection between Gauss and Maxwell" so the connection of statics was wrongly connected to the Gaussian law on" magnetics" and not his laws on "statics.".
>The boundary laws of Maxwell which is the basis
of all of his equations are also those of statics which, when made dynamic, are the one and the same equation arrived at by Maxwell . I know of no mention in any book on radiation that equates as fact that classical physics mathematically supports the position of particles as the root of propagation which is in agreement with Einsteins laws on Relativity. Point being that mass is required for "acceleration of charge" as with particles./ electrons
and to my knowledge has not been stated as the Gaussian connection to Maxwell..... anywhere!
>I would appreciate it if you or anybody can point to where I am in error and where your position can be determined as credible.

"Maxwell equations" have nothing common with Maxwell.
http://www.ivorcatt.com/2810.htm

"Heaviside said that mathematics was an experimental science. He organised Maxwell's mathematical work into the four equations which we now call "Maxwell's Equations".

All monopoles need an electrical reference point to be "driven against."

Using a symmetrical arrangement of two or more 1/4-lambda-resonant, horizontal wires elevated sufficiently above the earth provides that by acting at their junction under the base of the monopole as a point with constant electrical characteristics with respect to the current flowing in the antenna system.

NEC shows the peak free-space gain of such a system using a 1/4-wave monopole to be the same as that of a 1/2-wave dipole in free space, e.g., 2.15 dBi. When that system is operating within a few electrical degrees above a perfect ground plane then the peak gain rises to 5.15 dBi, because all of the radiation is re-directed/confined to one hemisphere.

Horizontal wires lying on, or buried several inches below the surface of the earth do not have the same electrical characteristics or function as when they are elevated. Instead, they serve to collect the r-f currents generated by the displacement field radiation of the monopole -- which currents flow in the earth out to about 1/2 wavelength from the base of the monopole.

If the earth was a perfect conductor then those currents could travel through the earth without loss, and a single, short ground rod would serve as an electrical reference point for the r-f current flowing in the antenna system. The sum of those r-f currents flowing in the earth around the monopole, and collected by that ground rod will be equal to the base current in the 1/4-wave, series-fed monopole. The gain of this configuration is 5.15 dBi, the same as when using a few elevated, resonant wires as a counterpoise.

But the earth is not a perfect conductor. For that reason it is necessary, when using buried radials, to install enough of them in the surface area out to about 1/2 wavelength to collect those r-f currents before they have traveled through much of the lossy earth to reach those wires.

The benchmark 1937 I.R.E. paper of RCA's Brown, Lewis and Epstein showed that 113 x 0.412-lambda buried radial wires used with monopoles of about 45 to 90 degrees in height produced a radiated groundwave field when measured at 3/10 of a mile that was within several percent of the theoretical maximum for a perfect monopole radiator with a zero-ohm connection to a perfect ground plane -- and this despite the fact that earth conductivity at/near their test site was not better than 4 mS/m.

As an aside: NEC analyses for far-field conditions show an elevation gain of zero in the horizontal plane for a monopole over real earth, and peak relative field gain at some elevation angle above the horizontal plane. However the radiated, relative fields that exist at, and relatively close to the edge of the near-field boundary of the radiation hemisphere of all monopoles of 5/8 wavelength and less are very nearly equal to the cosine of the elevation angle -- which value is 1.0 at zero degrees (the horizon), and zero at the zenith. If they were not, then the fields measured by BL&E would be much different than they recorded in their 1937 paper.

It is only after those fields propagate a significant distance over a real earth path that they depart significantly, and progressively more significantly with distance, from the relative fields described by the cosine value of the elevation angle.

Obviously a reduction in IR losses will improve any antenna. Art how
much do you thing making an antenna out of silver instead of aluminum
would reduce the IR losses.
Jimmie

I think I will back off and let you get back to the porn
without interruption since that is what you apparently want instead of
antennas talk.

Jim

Yes it is a multiband application. Why would I use an Icom AH-4
antenna coupler on a single band antenna?   What would be the
advantage to wiring it as a "fat dipole"?

As to why not put the coupler at the feed point I would point out that
the statement "The box *is* a
> bit heavy," would pass as a masters dissertation in understatement.  An e=
ntire center support would have to be created or I would have to rig a cate=
nary at the present support points and lower the antenna closer to the grou=
nd to permit the catenary  to take the weight of the antenna coupler.  I wo=
uld point out that this present Folded Terminated Dipole is not Tilted but =
instead is rigged as a flat top.  Height is might; so the old radio axiom g=
oes; so I would rather not have to lower the antenna just to avoid using la=
dder line.  Additionally in order to compensate for the bending of the tree=
s that support the antenna now I would have to rig a second counterweight a=
```

nd puller system to keep the antenna itself from being torn apart since the=
 first one would be in use to keep a constant tension on the catenary. Tha=
t is a lot of work in order to avoid the use of some ladder line that proba=
bly has a lower loss than the additional coax that would replace it.

Since the conductivity of aluminum is about 43 times higher than that of bisimuth, I think you are babbling.

Yeah, I too some of that from my neighbors yard, tried to make an antenna.

Cops came and took me away.

When I asked them why, they said it was none of my Bismuth.

InfraRed loss in an antenna?

or perhaps:

I�R Voltage Loss in an antenna?

or perhaps:

I��R Power Loss in an antenna?

****

Yes, I��R loss is the entire point (and positive characteristic) of an
antenna, especially if R is radiation resistance.

Hmmm, I�R loss could be said to be a naturally occurring fact of life
along the length of any antenna if we consider the distribution of
potential.

Ouch, InfraRed loss could burn you - but it would be curious to note
that if an antenna is truly an equal performer (transmit/receive) what
would we hear from the antenna when the sun rises in the morning?

As to the receive-mode phenomenon of this sunrise observation, if that antenna were coated with diamagnetic water (dew), then we would observe particles leaping (-um- steaming) off of it (with sizzle)!

Seems you have it backwards. The slow-moving free electrons oscillate back and forth at HF, moving forward and backward very little (calculate it for yourself). The energy flow from source to load is in

the form of photons/fields/waves traveling at the speed of light
which is impossible for electrons. As far as ham radio antenna
functions go, electrons and photons are the only things known to
physics to be active in transferring and radiating RF energy.

Symmetrical back and forth take place only in the simple equations.
In EACH wave the forth is stronger than back.

>The energy flow from source to load is in

Photons in a wire?

>As far as ham radio antenna
functions go, electrons and photons are the only things known to
physics to be active in transferring and radiating RF energy.

Electrons were discovered. Photons are the products of speculations.

No, you idiot.

Photons have been observed.

The intellectual product of a Stalinist education system.

Or the most lucid manifesto available from the Tea Party.

Ah, I almost forgot, it's election time.

Could you please let it go just one election season? It is boring and
repetitious crap and way beneath your normal responses.

First consuming Ayawaska and then putting on a 3d pair of glasses actually allows you to see the photons shooting out from the antenna. I believe it is the "time dilation effect" from the Ayawaska which is responsible for this, seemingly, "superman ability" occurring.

As always, first consult your local shaman or witchdoctor before taking
Ayawaska ...

Regards,
JS

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

"It was shown by Stokes that in a water wave the particles of fluid possess, apart from their orbital motion, a steady second-order drift velocity (usually called the mass-transport velocity)."

In all schools the second-order effects are neglected.

In Stokes time no radio. But the above apply to all waves.

You should start with the selfeducation.

Electrons, mass transport and the field emission are reality. EM is a myth.

Sounds like you are using a stream of salt water as a radiator! Is the
pump Bismuth coated to prevent corrosion?

> pump Bismuth coated to prevent corrosion?

In each radiator is a stream of electrons. The oscillating pump is in the transmitter. But where is the tank with the electrons?

It is in the buried or elevated radials. R. Roy wrote: "If the earth was a perfect conductor then those currents could travel
through the earth without loss, and a single, short ground rod would

serve as an electrical reference point for the r-f current flowing in
the antenna system. The sum of those r-f currents flowing in the
earth around the monopole, and collected by that ground rod will be
equal to the base current in the 1/4-wave, series-fed monopole"

The soil is different in each place. The air is similar. So the elevated
radials are universal. They catch the electrons from the air.

Hi,

A bit off topic, but I figure you folks are the true theorists out there, and would probably know about this.

Am thinking about purchasing a shortwave defined radio receiver from WinRadio (http://www.winradio.com/home/g33ddc.htm).

Here is copy from part of their spec sheet:

"The receiver's robust front-end is equipped with an ultra-high-linearity amplifier which results in exceptional strong-signal performance. This already robust front-end is further enhanced with a user-selectable preselector that can operate either in a fully automatic or user-configurable mode. As many as 119 different filter combinations can be constructed by the user (91 bandpass, 14 low-pass and 14 high-pass). The front-end employs 34 subminiature electromechanical relays (rather than often used but distortion-prone semiconductor switches) to ensure high dynamic range."

Was really surprised to see: The front-end employs 34 subminiature electromechanical relays (rather than often used but distortion-prone semiconductor switches) to ensure high dynamic range.

I am retired now, so haven't kept up withese things, or the state of the art nowadays, but are they still using electromechanical relays for front ends feeding a 16 bit A to D ?

Haven't semiconductor switches, caught up with reed relays for this application by now, or do they "still" provide a lower "on" resistance, etc. ?

Any thoughts would be most appreciated.

Thanks,
Bob

I have a lot of SW radios and amateur gear. When you have used a SDR, you are simply left with one question, "Why would anyone, anywhere, use anything different?

I mean, it is still fun to fire up an old one and watch the tubes glow ... nostalgia, I guess.

Forgot to respond to this part ... my whole experience with repairing electronic gear has been, first suspect a mechanical problem (switch, ground, etc.), then suspect a capacitor, then a resistor ... dead last is a semiconductor ... it is taken for granted that properly engineered equipment is the point of discussion ...

Propigation is always good on the internet. With a fast (15mbit download) internet connection why bother with a radio at all?

To be honest, I often don't. I skype chat, I call people on a VoIP phone, I email, I use facebook, I watch TV from around the world, I listen to radio from around the world.

TV and radio are especially nice because I can get the programs I want when I have time to pay attention to them.

I also use my radios because I want to. I expect different things from them and chalenges to get them.

To answer the original post, reed relays are relatively cheap and have very high isolation between the poles. Electronic switches are available and cheap but not with as good isolation (at least not at the price of the relays).

Geoff.

Actually from a manufacturing point of view it sounds like they have taken
the matching board from a "100 watt" automatic tuner and converted it to
a preselector/filter board by chainging the programing on the controller
chip.

In this case the "the front end ...." stuff is marketing hype.

If they got enough of them as a close out, it would be a cheaper than
having to make one from scratch, no matter what was in it.

Geoff.

Semiconductor switches have issues with intermodulation, etc. and power consumption. For wideband RF, you're not going to be using cheap 4066 CMOS muxes.. if you need to handle strong signals, that implies decent diodes with a fair amount of current.

High quality sealed relays are inexpensive, very reliable, etc.

Tom Horne wrote:

> As to why not put the coupler at the feed point I would point out that
> the statement "The box *is* a
>> bit heavy," would pass as a masters dissertation in understatement. An entire center support would have to be created or I would have to rig a catenary at the present support points and lower the antenna closer to the ground to permit the catenary to take the weight of the antenna coupler. I would point out that this present Folded Terminated Dipole is not Tilted but instead is rigged as a flat top. Height is might; so the old radio axiom goes; so I would rather not have to lower the antenna just to avoid using ladder line. Additionally in order to compensate for the bending of the trees that support the antenna now I would have to rig a second counterweight and puller system to keep the antenna itself from being torn apart since the first one would be in use to keep a constant tension on the catenary. That is a lot of work in order to avoid the use of some ladder line that probably has a lower loss than the additional coax that would replace it.
>

OK.. makes sense.. So you'd have antenna in the air, open wire line to tuner which is sitting on the ground or somewhere convenient, then coax to the rig.

As for loss.. open wire line is lower loss when matched than coax, but in the highly mismatched case, the loss might be greater than the loss of the coax, if you move the tuner.

This is kind of unintuitive, so we'll run some examples

What's the feedpoint Z of a 90 foot dipole in the various bands?
using W9CF's online loss calculator with 33 ft of 450 ohm window line
For 3.8 MHZ (24-541j), loss is 1.3dB (tuner sees 13.3-15.5j)
For 7.2 MHz (29+768j) loss 0.79 dB (tuner sees 11.6-247j)
For 14.2 (124-681j) loss 0.51 dB (tuner sees 135-663j)

For comparison 33 ft of RG-8X has .17 dB of loss (matched) at 3.8MHz, .25 at 7.2, and 0.35 at 14.2

Now, the question might be, what's the loss in the tuner matching 29+768j to 50 ohms (tuner at feedpoint) vs loss in tuner matching 11.6-247j to 50 ohms (tuner feeding 33 ft of 450 ohm window line to antenna)

W9CF's tuner applet says 0.3 dB for the first case and 1.7 for the second..

SO..

Tuner at	feedpoint	at ladder/coax transition
Loss in 450 ohm line	0	0.79
Loss in Tuner	0.3	1.7
Loss in 50 ohm line	0.25	0
Total:	0.55	2.49

That makes the tuner at the feedpoint almost 2 dB better..

Similar numbers for 3.8MHz
24 -541j 2dB tuner loss to 50 ohms + 0.17dB feedline = 2.17
13.3-15.5j 0.9dB tuner loss + 1.3 feedline loss = 2.2 dB

pretty much a wash

---- take home message>> 90 feet is probably a "bad" length to use for this application
---- take home message2>> open wire line is only low loss when well matched.
---- take home message 3>> it's worth it to put the matching network at the feedpoint, when there is a large mismatch.

Running a quick NEC4 model of a 90 foot dipole 10 meters off the ground

> antenna coupler on a single band antenna?

Because the wire length was fixed for some other reason (installation
convenience) or you wanted to operate over a wider band than a regular
dipole would be acceptably matched for..

(mostly because you suggested having the AH4 in the first place)

  What would be the
> advantage to wiring it as a "fat dipole"?

Wider bandwidth of the underlying antenna, so potentially lower losses
in the tuner.
Redundant wires in case one breaks.
Less modification of the existing antenna.

Art wrote: "What do you think?"

So I wrote that antennas are made of metalic conductors, salt waters and
live tree. It seem that material is not important.
The key factor is the oscillating, nonsymetrical flow of electrons. We need
the tank, the pump and an antenna. May be with or without Bismuth plate.

Really good relays are available at very low cost today. Like less
than a dollar each! Between the Low Pass filter and the inboard
antenna tuner my TenTec Jupiter there are about 30 relays.

Other than overrall circuit size and switching speed I see no
advantage for semiconductors as compared to relays.

As far as "Why Ham Radio instead of internet?" :
I worked Japan last night (not my first time) on PSK-31/20 Meters with
40 watts and off the side of the Beam. The feeling was not unlike my
first Ham Radio contact 50 years ago....

It is my kind of getting high!

I have been faithfully using a coil of coax as a common mode choke for
a while without any idea if it is really doing any thing.

Googling turns up more url's than I can follow. I would appreciate any
suggestions as to how might measure the effects of the common mode
choke. 30 to 17 meters is my favored range of operation. I have a
pretty well equipted shack.

That's because you are a babbling idiot.

The material is very important in the real world.

The implication by many is that the radiation particles or electrons
are extracted from the actual radiator.
Where did this notion come from and what is its justification?

Take one piece of wire;
loop it into a half-dozen loose turns (1" diam);
connect a Red LED to the wire ends;
place loop around coax;
slide it along the coax for a distance of something more than a
quarterwave length of the frequency under consideration.

How bright did the LED get anywhere along that length?

You would not be alone. They seem to be the most popular suggestion for dealing with common mode current issues, but I suspect it is often a case of "fools rush in where angels fear to tread". The anecodotal support for Ugly Baluns is not convincing, and quantitive measurements explain why.

They are cheap, and it is the only factor I see consistently shaping recomendations, cheap rather than effective in the application. Of course, doing nothing is cheaper, and better value if it is as effective!

Well, I better not give you any more references to follow.

The so called 'Ugly Baluns' are so popular, and peform so poorly. They achieve very high choking impedance around a narrow region about self resonance. If you have a narrowband application (eg single band antenna) AND arrange that self resonance at the band of interest, then they are capable of excellent peformance (very high choking impedance).

If your need is broadband operation, look to ferrite cored baluns.

As far as measuring common mode current goes, people have described common mode current meters, and some are available commercially. The problem is that common mode current is a standing wave, and a single measurement (at a single location) says very little.

The indirect effects of common mode current are not so easy the 'measure' as such, but you can asses the impact by things like sensitivity of line VSWR to line length and placement / routing, RFI to ham shack gear, other household equipment, neighbors equipment etc. You might also try to assess degradation of ambient noise due to common mode current. Distortion of transmitted pattern is more challenging to assess.

Owen

"... for a copper wire of radius 1 mm carrying a steady current of 10 amps, the drift velocity (of the free electrons) is only about 0.024 cm/sec!"

The key factor is the generation, by the oscillating electrons, of RF photons/fields/waves (traveling at the speed of light) .

there is no justification, just mr.b's delusion that is even worse
than your levitating neutrinos.  He thinks that its the actual
electrons that jump off the antenna and flow to the receivers.
Now ain't that a gas?

YES!  i have done that and it works great... even better than
bedsprings because you can make it vertically polarized by feeding in
the right place.

Well we do have opinions exceptpenniokio but where is the backup data?
I would imagine that some old timers are getting near the end of their
antennas life, as what started with a thick radiator has now got down
to a couple of mills and drooping
```

and only a few electrons left.
On the other hand it is well established that billions of particles
inhabit every cubic metre on earth and the question is that if we
don't allow these particles or neutrinos to settle or rest a dense
fog is going to envelope the earth killing mankind and allowing the
dynasaurs to come back. We already have some dynasoars in the making
on this thread!

N6LF made extensive measurements and essenstially confirmed this. He
wrote a 7 part series of articles for QEX. You can download them at
his site:
http://www.antennasbyn6lf.com/2009/12/series-of-qex-articles-on-ground-system-experiments.html

> This leaves me wondering why the popularity of extensive fields of
> buried radials for the lower bands.

Practicality. In most cases, you either want to be able to walk above
the radials, (i.e. bury them or leave them on the ground) or below
them. This means at least 2 - 2.5 m up, and there will be some
sagging. Essentially, your vertical just got that much shorter. But if
what remains is tall enough, it's a great choice. If a friendly farmer
lets you borrow a field in wintertime, stringing four elevated radials
is a lot less work than rolling out 32 on the ground.

Hi Jon,

Noted.

One of the designs I am exploring is an eighth wave vertical over
elevated quarter wave radials, three top guy ropes the the radial
straining posts, and the top section of the guys are top hat wires. The
whole thing is tuned low so that it is matched to 50 ohm line with a

shunt inductor. Modelled performance is within 0.5dB of a ground mounted quarter wave with 32 buried radials. Elevating the radials with the shortened vertical is not a big structural challenge, even to 2.5+m to allow a bit of sag in the radial catenary. (I never said I wanted to rig the radials at 100mm, just that above that, the efficiency was relatively high and didn't vary much between 100mm and a few metres.)

But, such a design does not conform to the Rules of Thumb commonly trotted out for low HF Marconis.

I will look at Rudy's articles, always an interesting read.

Thanks
Owen

People generally don't have the room to have several elevated radials
1/4 wave long for 20/30/40/80m whereas the buried ones can be laid in
any shape required to fit.

--
Conor

I'm not prejudiced. I hate everyone equally.

I haven't done any careful measurements, but one of the books
I have has an article and graph that pretty much matches the
figures I gave as far as amount of elevated radials needed to
match a certain amount on the ground.
I'm not sure which book it is..
Maybe one of the Bill Orr radio or antenna handbooks..
I don't think it was the ARRL handbooks.
But I have tried exactly what you are proposing. And it didn't
really pan out too well. I could hardly tell the difference between
having them on the ground, and slightly elevated.
Sure, it worked OK, but it didn't mimic a large number of radials
by any means. I also tried the elevated ground plane at various
heights using the same four radials. You could tell an obvious
difference between 1/4 wave up, and 1/8 wave up using the same
four radials. The real world results I've seen seemed to fairly
closely match the graph I have in that book.

BTW, I know it was one of the Bill Orr handbooks which
suggesting trying the elevated low radials.. I think the
same one that had the graph. He seemed to suggest it
was better than having them in the ground. But on the
other hand his graph dealing with elevated radials
suggested the results would be fairly lackluster.
Which they were at this QTH. :(
Now that I think about it, I think it was the Bill Orr
antenna handbook that had that article and graph
pertaining to the radials.

Being as you are talking about radials which are very low,
I assume the base of the radiator will be low also.
Myself, I think a large part of the lack of success I saw
was due to not enough radial density at the base of the low
vertical. I think one would probably be better off taking
the three or four 1/4 wave radials and chopping them into
many short radials and laying them on the ground.
And this is indeed a fairly common practice when laying
them on the ground.

I think having the higher density of wire at the base works
better than have just a few radials elevated. Most of the
ground loss seems to be in the area of the base.
I know metal density under the radiator is quite critical as
far as short mobile whips.
I saw that when I tried mounting my mobile whip on a

piece of angle iron that was running across the bed of
my truck. It didn't work too well, and being I was used
to using that antenna on various mounts, it was obvious
something was wrong. And the angle iron was very
well grounded as far as bonding to the truck.
That wasn't the problem.
I then moved it over to the top of the side mounted
utility bed box, which is a part of the truck body and
a good bit wider, and my usual performance was back.
Just by adding more metal under the base of the whip
did the trick.

I think this is one reason why I always had so much
better results with elevated vs ground mount verticals.
At 1/4 wave up, the base of the antenna was much
farther from ground, and the antenna started to
perform more like a vertical dipole, than a grounded
monopole.
With the ground mount, I was up to 32 radials at
one point. And the performance was still mediocre,
and barely better than my dipole at 36 ft on longer
paths.
Only when I got it up at 1/4 wave did it really come
alive. After that, it ate the dipole for lunch on longer
paths, and with only four radials.
All of my comparisons were done using a full 1/4 wave
radiator.

Anyway, maybe your model is more accurate than I
think. But I've already tried doing that, and wasn't too
impressed with the results.
I've heard others that tried it also, with the same lackluster
results. I think elevated or not, it's just too few a number
of radials to really be effective at that low height in WL.
Too much lossy dirt between the few radials is my
theory.

I just don't believe in too much of a free lunch when it
comes to just a few radials at low heights in wavelength.
My stance comes from actually trying it, vs modeling
it. I don't totally trust the modeling programs in
this area. I've seen too many differences comparing
the models vs the actual vertical antennas.
For instance, using "average" ground, most of the
programs underestimated the performance of my 1/4
wave high ground plane. To get a model that more closely
matched real life vs my dipole, I had to set the ground at
a much higher conductivity.
And in the case you are modeling, it seems to be
over estimating the performance vs real life.
Or at least what I have seen after trying it.

I wished it would have panned out better. Would save a lot of wire. But for me, the improvement was minimal. But.. You are welcome to try it. Maybe you will have better luck than I did.

This topic was investigated experimentally quite some time ago by a broadcast consulting firm in the US, which generated measured data. Here is a clip from their paper describing the system tested, and the results (note that the convention used for "efficiency" here is that of the FCC practice based on the groundwave field intensity at 1 km with respect to the power applied to the antenna system):

\\ In November of 1988, our firm supervised the construction of a temporary antenna system in
Newburgh, New York under FCC Special Field Test Authority using call sign KPI-204. The antenna

system consisted of a lightweight, 15 inch face tower, 120 feet in height, with a base insulator at the 15 foot elevation and six elevated radials, a quarter wave in length, spaced evenly around the tower and elevated 15 feet above the ground. The radials were fully insulated from ground and supported at the ends by wooden tripods. Approximately ten feet above ground, a T network for matching the antenna was mounted on a piece of marine plywood to isolate the components from contact with the lower section of the tower which was grounded. Power was fed to the system through a 200 foot length of coaxial cable with the cable shield connected to the shunt element of the T network and to the elevated radials. A balun or RF choke on the feedline was not employed and the feedline was isolated from the lower section of the tower. The system operated on 1580 kHz at a power of 750 watts.

The efficiency of the antenna was determined by radial field intensity measurements along 12 radials extending out to a distance of up to 85 kilometers. The measured RMS efficiency was 287 mV/m for 1 kW, at one kilometer, which is the same measured value as would be expected for a 0.17 wave tower above 120 buried radials.

The Newburgh tests gave empirical proof that the elevated system worked although, in an abundance of caution, we used six radials instead of four. For the limited time that the system was operational, the system was stable as determined by monitoring the field intensity at selected locations each day. The measured base impedance was in general agreement with a tower of this height above a standard, buried, ground system. Results of the KPI-204 tests were submitted to the FCC in January of 1989.//

I would think that the buried radials are more convenient (broad band, etc.)

Look at the performance of your ankle biting radials when the dimensions are changed slightly..   For instance, if you shorten them by 5%, does it make a big difference? For the buried radials, the length is very, very non critical.

Something else to look at is the sensitivity of "efficiency" (and your definition of radiated power in the hemisphere/power into antenna is fine) to soil properties.. if the soil conductivity or epsilon changes (as it will with changing water content) does the efficiency change rapidly?

Also, what about the loss in any matching components needed (e.g. if you had a real efficient narrow band antenna, then operating off nominal means you'll need a different matching network, and the loss in it might be worth considering)

Hi Richard,

Solid piece of information - thanx.

Odd to notice none have acknowledged field data.

Thanks Owen,

In this case I had it down the middle between the haves, through clips.

Does that disturb the characteristic impedance of the spine transmission
line? If so, does that contribute to the problems you observe?

If this LP is mounted to a mast somewhere forward of the rear element, I
would consider dressing the feedline away from the feed point at right
```

angles to the spine, installing a common mode choke near the feedpoint,
and bringing the feedline to the mast some distance below the spine.

If you were to perform a test where the LP is mounted a wavelength or
more above ground, pointing to the zenith, feedline falling downwards
from the feedpoint, common mode choke near the feedpoint, it would
reveal whether the array is working as intended. If your actual mounting
causes it to work differently, you know where the problem is.

Owen

Yes, I understand that there are advantages to buried radials, but I don't understand the preponderance of cases where I see 120 radials pinned on the top of infertile dirt. They still present a trip hazard, and less money spent on just a few elevated radials may perform just as well.

Yes, of course the feedpoint impedance is more sensitive to change in length or conversely change in frequency.

Yes, efficiency is sensitive to soil parameters... for both types, but not very sensitive.

Because of the impedance change mentioned above, the impedance transformation needs adjustment for wide range frequency operation. Not such an issue in the intended application, the DX window on 80m here is just 50kHz.

>
> Also, what about the loss in any matching components needed (e.g. if you
> had a real efficient narrow band antenna, then operating off nominal
> means you'll need a different matching network, and the loss in it might
> be worth considering)

Matching network loss was not included in my analysis because both quarter wave options present fairly similar load impedances that need transformation to 50 ohms. The shortened verticle is slightly lower R (23 vs 38 IIRC), and slightly more loss can be expected, but it is practical to match with a shunt coil of copper tube and matching loss should be real low in the system context, and in comparison of elevated vs buried radials.

If I haven't got something quite wrong in the modelling, it would seem worthwhile to prototype the shortened version with a view to extending the system to a four-square if suitable.

I have still to read Rudy's papers... I am away from home (less bandwidth) and I will download them later today when I get home. I suppose that the proposed design challenges the norm of a very large number of buried radials. In our case, part of the property is quite rocky, and a configuration with just a few elevated radials offers deployment opportunities that aren't suited to buried radials.

So, my original question is no so much suggesting everyone else got it wrong, but why don't I seem more people doing it this way. Could I be forgive in thinking that the popular, nearly universal, way is to uplift the BL&E research at MF and apply it to 80m?

Owen

The BL&E experiments were conducted using 3 MHz signals, so their applicability to the 80m band is not a large uplift.

Well, it does different things based on how the cable is routed, but
none are really better than the other... just different. I tried
coming off the back, and also at the mid point... It changed, but not
better or worse overall... The points of good and bad just changed
position across the range.

I'm going to try the ferrites. What do you think about these?

I stand corrected. I have read the paper many times, and my recollection
was that it was below 2MHz. Must be time to read it again!

Owen

never underestimate the power of tradition. It was written by BL&E that
120 radials work, and the FCC accepts that for broadcast, so by golly,
that's what we do. Why 120? it was at the point of diminishing returns
or practicality back when the study was done (e.g. there was no
detectable change from going to more)

As for laying on ground.. I think that's more the laying on grass, and
eventually, the wire sinks into the grass/turf.

There's also the whole "the radials must be resonant" misconception..

While for a buried radial system (probably because of the losses) it's
going to be less frequency sensitive.

Maybe less sensitive for the buried radials? Or, it was "good enough" for BL&E, so being so written, so shall it be done.

The shortened version will, of course, aggravate the tuning sensitivity.

Tradition is a powerful force. Look how many years it took for someone (e.g. Rudy) to put the substantial work into doing a real quantitative experiment. For most hams, they're only going to do something once, and if works ok, that's how it stays. Almost none are going to do a well controlled A/B study, especially if there's a (not necessarily valid) tradition that says A works better (where better is ill defined and probably a combination of radiation efficiency and installation convenience)

Until recently, modeling tools available to most amateurs were not suitable for making the call, although there have been some people who did models and published it, but, in the face of decades of "lay down 120 radials" it was a tough sell.

The other thing is whether the difference is big enough to "make a difference" in observed system performance. For a lot of operators, a 1 dB change in performance might not be noticeable. If you're in a

"either propagation is there, or it isn't" situation the difference
between good and bad is 10s of dB. There are relatively few people who
work at 0dB SNR (where tenths count) on a regular and continuing basis,
and they're not necessarily the ones who are interested in doing
experiments on antennas on the scale needed.

The one question I've not seen asked is how close to what you built is
your model? Everything is critical at those frequencies and as little as
1/32" can make a difference. If your model doesn't match exactly the
antenna then it's no wonder it's not working as expected. To me modeling
the phasing lines between the elements be they separate from the boom or
are the boom is one of the trickiest parts. As an example if you used a

1" square boom and modeled it as a 1" diameter wire there would be a
problem. They are not equal.

The original field research was done at 3 MHz - very much closer to
80M than to 300M.

BL&E were measuring ground wave, I think solely. My efficiency measure
is the hemisphere, so ground losses play a different role.

Yes, but the model suggests that the variation in R is very small, and
variation in VSWR (with shunt coil match) is small... in that band segment.

Yes, there will be differing view on what is significant difference. I
am not in the school of declaring less than one or two S points is
insignificant in general.

In the case of a four square in the DX segment, users are looking for
performance... and it seems to me that the elevated three radials, eight
wave vertical with capacity had is very close to quarter wave over
buried radials... depending of course on the soil type.

You mention the modelling tools, I am not so much concerned as to
whether the elevated radials model is good, but whether the NEC4 buried
radials model is good, and likewise for radials on and just above the
ground because those models are setting the benchmark for the
performance of the alternative.

Hi

Wanting to put up the CHannelmaster HD antenna 8bay

I have heard some about putting two up. Each aiming towards a different major city to get the best reception for the HD.

Any advice on this? Any reason to or not to or better ideas?

Thanks

A minor point, but in the interest of accuracy - the greatest number of buried radials used in the BL&E experimental work was 113.

> There's also the whole "the radials must be resonant" misconception..

While the physical lengths of the buried radials in the BL&E experiments were stated in free space wavelengths, that does not mean that those physical lengths will behave the same when buried as they will when not buried.

As shown in the link I posted earlier in this thread (and by NEC), a few elevated wires used as a counterpoise in place of the BL&E buried wires need to have an electrical wavelength of 1/4-lambda for best antenna system radiation efficiency, even with "short" vertical monopoles. And even when those elevated counterpoise wires are close to the earth in terms of a free space wavelength, their electrical length is not much different than their physical dimension in terms of a free space wavelength -- as is the case when they are buried.

Theory and practice both show that such wires perform differently when they are buried than when they are elevated above the surface of the earth.

you can get rotators to turn a single antenna.  the price is probably
about the same, 2 antennas, feedlines, and a switch, or one antenna
and a rotator.  it may also depend on what you have to mount the
antennas on.

Yes, thanks for the comeback

I wanted to stay away from a rotor as both my cities of market are in good direction to point.

The store says the cable tee will work for the splitter or switch.

Just looking for a second opinion.

THanks

> N6LF made extensive measurements and essenstially confirmed this. He wrote a 7 part series of articles for QEX. You can download them at his site:
> http://www.antennasbyn6lf.com/2009/12/series-of-qex-articles-on-ground-system-experiments.html

Hi Jon,

All of the articles are interesting. I have previously read the last, but wasn't aware it was only one of a series.

Looking at Article 3, Fig 1 suggests that efficiency improves very slowly beyond about 32 radials lying on the surface, and 4 such radials are about 5.4dB below 32 radials.

In Fig 2, he shows 4 radials just 6" (150mm) above ground as about 5dB better than 4 radials on the ground.

My interpretation of Fig 1 and Fig 2 then is that 4 radials at 6" are about 0.5dB behind 32 radials lying on the ground. That is the type of effect I was referring to when I said "If my models are valid, and they use 'average ground', the indication is that while it may require a large number of buried radials (>16) before efficiency levels off a bit, similar efficiency can be obtained with just three radials elevated more than 100mm above the soil" in my first post.

Rudy reports some further small improvement (<1dB) in raising the radials to 4'(1.2m).

These are very similar effect to those predicted by my NEC4 model. In the case of my model of radials from 100mm depth to some distance above ground, the improvement was mostly in the range of heights from 0mm to about 20mm. Obviously, the model is sensitive to soil type, and different soil types can be expected to yield different response... but it would seem that just 3 radials at 1 to 3m height give similar system efficiency to 16+ radials shallow buried for a range of common soil types.

I know my interpretation of Rudy's measurements and my NEC4 model don't fall in line with some traditional thinking, and will not appeal to many.

I think it is time to build a prototype.

Thanks for the links.

Owen

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Would love to see fotos of the antenna you built.
Is there a stub at the end or is there a termination resistor?

The two links below may be of interest in comparing NEC modeling with empirical results.

The first link is a clip from the "benchmark" 1937 I.R.E paper of BL&E, showing that the radiated fields measured 3/10 of a mile from monopoles ranging from about 45 to past 90 degrees in height, and using 113 each 0.412-lambda buried radials is within several percent of the theoretical maximum for a perfect monopole of those heights when driven against a zero-ohm connection to a perfect ground plane. The BL&E tests were conducted in the sandy soil of New Jersey, where earth conductivity was/is 4 mS/m or less. Those measured results indicate those systems were radiating 90% or more of the applied power, and that the conductivity of the earth in which those radials were buried is relatively unimportant.

The second link is a NEC model of a 1/4-lambda monopole driven against four, elevated counterpoise wires with no antenna system connection to a perfect ground plane, showing that its peak gain is 5.15 dBi -- which is the theoretical maximum for a perfect 1/4-lambda monopole driven against a zero-ohm connection to a perfect ground plane.

Adding an ohm or two in the connection from the source to the four elevated radials reduces the gain/field of the NEC model such that it is approximately what was shown in the BL&E study, indicating that a similar value must have been present in their buried radial ground system consisting of 113 each 0.412-lambda wires.

Using NEC-4 to incorporate buried (or elevated) radials into the model should show groundwave fields within 1 km of the monopole that are very close to the theoretical maximum for the applied power when radiated along a perfect ground plane, if the model is optimal, and accurate.

The theoretical maximum inverse distance voltage field intensity at 1 km for 1 kW of radiated power from a perfect 1/4-lambda monopole system is about 313 mV/m.

Owen wrote:

> So, my original question is no so much suggesting everyone else got it wrong, but why don't I seem more people doing it this way. Could I be forgive in thinking that the popular, nearly universal, way is to uplift the BL&E research at MF and apply it to 80m?

There are lots of reasons that people don't use elevated radials versus buried ones. But before that, keep in mind that comparing elevated to buried is not really comparing 4 elevated to 120 buried. 120 is overkill, and not many of us who have verticals have that many. I found that 32 was getting into diminishing returns for me, so stopped.

Also buried radials are more forgiving of length variations. My case was that the antenna had to be located a good bit closer to one end of the yard than the other. So the radials on one side were from 10 to 25 feet shorter.

Also, many of us are married, and the spouse doesn't like all that many wires running around. My wife also mows the yard, something that would be relegated to me if I had a lot of wires running around the yard.

And I've used and been around an elevated radial system. It was a royal pain. You have to declare a rather large area off limits, we added little ties to it to warn people, and it didn't really help at night. That experience told me that elevated HF radials was not the way I wanted to go - ever.

Even if you are way out in the middle of nowhere, an elevated radial vertical is a liability unless you put a wire link fence around it - check with your insurance company.

Just my opinion of course, but it seems to be shared by many.

So with the buried radials not being all that much more work,(unless you insist on 120 of them) the greater flexibility of buried radials when dealing with real estate limitations, the appearance and liability issues, just makes a buried radial system a more attractive and practical option to many of us.

I would like to model the Channel Master CM4228HD Antenna with EZNEC.
It looks like a good deal to me at its price.

I need screen to Bow ties distance

length of bow ties

I think the distance between the bowties will be either 1/4 or 1/2
wave (from picture)

I think the included angle in each of the bow ties is about 30 degrees
as pictured.

The phasing lines are obvious from the picture.

There is a picture at
http://www.digitalhome.ca/forum/showthread.php?t=95467

Of course I will share the model!

It may do, I can not comment. My interest is for an antenna for sky wave path, and I have not explored ground wave performance.

In the cases of 32 buried radials and three elevated radials, the patterns are similar, efficiencies are similar, and maximum gain is similar. Reducing the number of buried radials degrades its performance significantly.

The elevated radials configuration allows a shortened radiator with capacity hat with negligible degradation in performance. I haven't modelled the same thing over buried radials, but I expect performance degradation would be significantly worse.

Owen

I stand corrected.. thanks..
So they extrapolated to 120 as a "nice round number" for the future
purposes of the FCC.

The only reason the FCC used 120, is overkill for the
stations to be able to avoid a costly survey.
If they didn't use 120, they had to do tests to prove
that the system was efficient enough. So most used
120 to avoid all that.
For most cases, 120 is almost twice overkill..
For ham use 60 is usually plenty to get well into
the near optimum range. Any more than that is
a small increase, and usually not worth the cost
of the wire.

Since Owen posted this question, I did a lot more
checking around, and I had already seen the MW BC
examples.
Seems I'm not the only one that doubts that a small
number of barely elevated radials will give a large
increase over ones on the ground.
One that is in my camp is... Yuri will love this..
W8JI.. Tom seems to agree with my stance from
what I can tell. He has done tests in this regard
and his results did not show much of an increase
over the ground installed radials.
In fact, he gave one example where they changed a
MW station from four elevated radials to the usual
buried radials.. I assume 120 of them..
They then had to explain to the FCC why the buried
radials suddenly gave 5 db+ gain over the supposedly
"near perfect" elevated set.. :/
He also did tests on 80m comparing this same thing.
The results did not pan out and pretty much were in
the same ballpark as the results I saw when I tried it.
IE: the elevated radials are slightly better than the same
number on the ground, but only by a small amount.
His tests showed that the usual buried radials using
60 or more greatly outperformed the three or four
elevated radials. By 5 db+..
Myself, I think for four elevated radials to equal even
sixteen on the ground would require them to be almost
1/8 wave off the ground.
So it seems I'm not alone in my doubt of this
supposed free lunch program. W8JI seems to be
in my doubtful camp. A few others too actually.

There might not have been much "discussion" though it is mentioned, but
the summary does contain the following:

"It is also found that a ground system consisting of 120 buried radial
wires, each on half wave long, is desirable".

It does appear that if someone blessed the number 120, it was probably
BL&E who did it, even if they were talking about half wave radials.

I think you can take the fact that Rudy's measurements match the model
pretty well as experimental validation of the model. indeed, NEC4 works.

Traditional thinking (or more accurately, mindless repetition of
tradition) could well be wrong, eh?

For broadcasters, sure.  But the discussion is in reference to the
potential performance difference for ham use, and I would think that
there is more than 1 dB variation in the "other end" of the link.  The
hard core DXer or QRPer digging the signal out of the noise will care,
but that's a small fraction of the overall ham population.

yeah, but there's a big difference between 6-12 dB and 1dB.. I think
most users would care about 6 dB.  Many fewer about 1 dB.  And even
fewer care about 1 dB AND have the desire and means to perform the
experiment in a controlled way. (well, this latter category probably has
less than 10 people in it, and only 1 has published in the last 50 years)

>

> buried radials... depending of course on the soil type.

Hmm.. and there the real question is what kind of performance are we
talking about: the power radiated in a desired direction (Tx) or the
ability to null unwanted signals (Rx).  Given the generally high noise
levels on low bands for Rx, a 1 dB change in efficiency of the antenna
might not make any difference for the latter.
```

A bigger effect on a phased array is the relative phasing. For a 4 element array, you can have pretty big errors in phase on transmit without changing the forward gain much (30 degree phase error on one element might give you a 1dB change). But a 30 degree phase error on receive could turn a -30dB null into a -7dB one..

And for that, the lower loss of your elevated radials might make things "pickier".. that is, as frequency or surroundings change, the reactive term for each element changes, which could change the power distribution and phasing among the elements (depending on the feed system used). (obviously, one of the "current forcing" drive schemes would be less sensitive to this)

The modeling performance of NEC4 for buried wires and wires just above the surface is quite good. Where I would be suspicious is for a wire ON the surface or partly embedded in the surface.

Look for that paper by Burke and Poggio on validating NEC3 and NEC4 (it was published at some conference in Ankara Turkey)

Thanks Jim, all fair comment and noted.

The end application is a four square phased array for the 80m DX window.

The location is at another ham's property, a rural location with ground ranging from dryish clay to rock.

I do expect noise to be lowish compared to residential precincts.

The excercise is really about a design for a monopole that gives reasonably good performance if extended to the four square configuration.

Yes, I note your points about the phase sensitivity to components. That would be a challenge even with buried radials as although we have been in drought for a long time with 'controlled' low moisture content of the soil, rain changes that and the soil is no longer as homogenous.

Nothing is as perfect as a modeller's world, but the discussion and some of the links offered give confidence that a shortened vertical with capacity hat and three radials, and shunt coil matched should give similar performance to full quarter wave verticals with 32 buried radials.

I have just reread Cebik's article on buried radials, and my own models seem fairly consistent.

As you say, Rudy's work is further confirmation allowing for the difference in configuration and the |S21| use.

Owen

Just to point out that for vertical monopole heights of 5/8-lambda and less, the peak elevation plane relative field (E / E max) _always_ occurs in the horizontal plane, regardless of the r-f losses in the buried radial system or counterpoise wires they are driven against, and the conductivity of the earth in which those radial wires are buried, or above which they are elevated.

IOW, the relative field actually "launched" at all angles above the horizontal plane from such antenna systems _always_ is LESS than that in the horizontal plane. The reason for this is related to the r-f current distribution, and its relative phase along the lengths of those monopoles.

NEC analyses showing low to zero relative field in the horizontal plane being launched by a monopole of 5/8-lambda height and less and regardless of the r-f ground they are driven against need to be understood in due context. The link next below leads to further development of this ...

http://i62.photobucket.com/albums/h85/rfry-100/MW_ElPat_Compare.gif

The longest, great-circle, single-hop, skywave paths are related to the relative fields launched by a monopole system at elevation angles of less than ten degrees (see Figure 55 in the link below) -- where a NEC analysis may show very low relative field.

But if such low relative fields really were true for the fields actually launched by such monopoles, then the nighttime skywave coverage of MW AM broadcast stations would be much different than is shown by real-world experience (and applicable theory).

John Ferrell <jferrell13@triad.rr.com> wrote:
|
| I would like to model the Channel Master CM4228HD Antenna with EZNEC.
| It looks like a good deal to me at its price.

Ken Nist (KQ6QV) has done a lot of TV antenna modelling with EZNEC, and many of his antenna models (*.ez) are available on this page:

http://www.hdtvprimer.com/SIMS/

However, the CM4228a.ez on that page probably is the old CM4228 rather than the new CM4228HD. His page analyzing the new CM4228HD antenna is:

http://www.hdtvprimer.com/ANTENNAS/TemporaryPage.html

His main page comparing commercially available antennas is:

http://www.hdtvprimer.com/ANTENNAS/comparing.html

Holl_ands has done a lot of modelling (using 4nec2), including the new CM4228HD (this page has his 4nec2 model files):

http://imageevent.com/holl_ands/multibay/8bayrefl/cm4228hd

| http://www.digitalhome.ca/forum/showthread.php?t=95467

Also on that site is an entire forum thread for modifying the new CM4228HD:

http://www.digitalhome.ca/forum/showthread.php?t=103749

John, further searching should turn up more information and details. AFAIR, the reflector on the new model facilitates reception on the VHF-hi band, which may or may not be sufficient (it is, afterall, designed for the UHF band). Too, there are a lot of DIY options...

Best Regards,
Chuck

Hello,

I have the normal lightning arresters for my outside (receive only)
antenna, but am still worried.

It has proven just about impossible to have my son to remember to
disconnect my receiver when lightning and thunder is nearby when I am away.

Was thinking about putting in one of those A/B switches (please see:
http://www.grove-ent.com/SWC01.html) that Grove sells in the antenna
line next to my Receiver.

This, being so simple, perhaps he can remember to switch to the Off
position. Maybe ?

I realize that if there is any strike nearby, and it gets thru the
arrestors, this switch being in the off position isn't going to do much
of anything.

But it might help for "low" voltage surges, etc.
What do you think ?

My main question: would it help even more if this Off position grounded
the antenna ?

Thanks,
Bob

How come ?
Can you elaborate how can these differences happen ?

Thanks

well, if your son can't remember then why don't you just disconnect when you leave. i tried having my dog disconnect, but he has a poor memory for that also and usually hides under the table when there is thunder.

otherwise, if you don't trust the lightning arrester you have, why have it? if it doesn't stop the transient then any switch inside probably won't either. grounding again inside is also a problem, if the current is inside already then sending it to another ground probably won't help, it will just go somewhere else.

Hi Bob,

Research this group through Google for methods of building a grounded antenna: loop, shunt-fed, folded dipole/monopole, etc.

OR

Build an electronic switchable antenna switch (AKA relay) that is only connected to your antenna when someone's butt is planted in the chair.

it's the difference between the effect on a peak vs effect on a null.

consider a simple 2 element array.. for sake of argument, say it's 1/4
wavelength apart and phased 90 degrees, so it has a cardioid
pattern.... a gain of 2 in one direction (where the signals from the
two antennas align), and a gain of zero in the opposite direction.
The gain is 1+cos(phi - spacing*cos(theta)) where phi is the feed
phasing, and theta is the direction.. in the preferred direction
1+cos(90 - 90*cos(0)) =3D 1+cos(0) =3D 2
```

in the 45 degree direction: 1+cos(90-90*cos(45)) =3D 1+cos(90-90*.707) =3D 1.895
in the 90 degree direction: 1+cos(90-90*cos(90)) =3D 1+cos(90) =3D 1
in the 180 degree direction: 1+cos(90-90*cos(180)) =3D 1+cos(90-90*-1) =3D 1+cos(180) =3D 0

Now spoil the feed phase (phi) by 10 degrees... (80
on boresight: 1+cos(80-90*cos(0)) =3D 1+cos(-10) =3D 1.984
on 45: 1+cos(80-90*cos(45)) =3D 1.959
on 90: 1+cos(80-90*cos(90)) =3D 1.174
at 180: 1+cos(80-90*cos(180)) =3D 1+cos(80+90) =3D 1.52E-2

The gain on boresight didn't change much... from 2 to 1.984 (0.03dB)
But the null in the back came up from zero to 1.5E-2.. (instead of -infinity, it's now -18dB)

Change the phase error to 45 degrees...)
@theta=3D0: 1+cos(45-90*cos(0)) =3D 1.707
@theta=3D180: 1+cos(45-90*cos(180)) =3D .292

So, from the 10 degree error case, the forward gain went from 1.984 to 1.707, about 0.6dB...
but the null went from 1.52E-2 to .292 (from -17dB to -5 dB)..

The thing to remember on any gain antenna is that it takes very little power to disrupt a null (after all, a -30dB null means that if you're radiating 1kW in the forward direction, you're radiating 1 W in the null.. so just another watt will double the energy in the null, turning it from -30dB to -27dB...)

(And, you can see why making antennas with sidelobes <-60dB is VERY challenging...)

Now, change the phasing to, say, 80 degrees.. in the preferred direction, the gain is now 1+cos(10degrees)

Thank you!

I am going to have to spend some time with these. My EZNEC + 5 does
not like all of the .EZ files but there is plenty of meat there to be
dissected. My interests are academic in the antennas. I don't spend
much time watching TV these days.

I have not looked for .ez file examples for a while on the net. When
last I looked, most of the sites I found were only interested in
selling models. Being an old time frugal Ham I am very cautious with
my hobby dollars!

Remember the first set you made from the scavenged parts of old radios
and TV's? Remember the excitment of your first piece of old military
gear, reworked and placed into service? Remember mail ordering tuning
caps, filtering caps, tubes for that first big amp?

Good on you mate! Those were the days when amateurs were hams and men
were men--heck, even the boys back then were men by todays' standards!

Sounds like you had it right, did it right, and are still doing it
right--to me!

Regards,
JS

The narration says he's 30 miles from the repeater.  He dialed up the
"OTAY" memory on his HT and the 146.640 machine is on Mount Otay, near
the Mexican border and well inland.  He is definitely line-of site to
it from anywhere around the bay,

What would be most interesting, and an assistance to your average
amateur, is have him tie a string which is somehow attached and held
fast but blown in an upwards direction, within the stream of water.
Then, you finally have the ability to tune, load and communicate on the
proverbial "wet string!"  And, vindication of all those who have claimed
such in old times ...

One small step for him, one giant leap for amateurs! <yeah!>

Regards,
JS

Evan,

I've done that with an 80 meter loop. It's far from the 'best' 160 meter antenna, but it can work 'okay'. How well it works (with in limits) depends a lot on how it's erected and the 'ground' you work it against. Too much variation in all that to make a guess about, so try it and see.

Paul

I have two NEC 536300 relays for sale. The specs are:

50 ohms input and output
150 Watts to 470 MHz
VSWR 1.25:1
Crosstalk 40 dB
12 VDC coil
Shown in August 1965 VHFer if you still have it. I don't.

They can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz   click on photo to enlarge it.

I'm asking $10 each plus shipping.
===
I have a Heath HM-2102 VHF SWR meter 50-160 MHz
0-25 and 0-250 watts. Very good condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

```

Anybody have experience with the "half delta loop" as shown here:
  http://www.qsl.net/va3iul/Antenna/Wire%20Antennas%20for%20Ham%20Radio
Wire_antennas_for_ham_radio.htm ?
  I modeled it in EZNEC and it seems to solve my space and support
problems on 80/75, and is decent on 40.  Patterns get kinda weird on
20M and above.

> auroras after a few days.
> S*

Sorry S* I did not read this post (I have to solve aome problem with
Google "tree view").

When I talked about ions I do it thinking in electrolytes containing feee heavy ions, not isolators.

My doubts with "mass" are about radiation of heavy ions with low electric fields. Larmor analysis shows radiaton of ions must be various orders of magnitud below radiation of electrons at lower electric fields intensities because its larger mass. We need higher electric fields intensities to get accelerations capable of radiating equivalent power obtained from electrons with lower E fields, then I believe they are not responsibles of useful possible EM radiation in our conditions.

Athough I have built ionic 50 ohms dummy loads with salt and water, then, I saw it is possible to establish VHF frequencies currents in such electroytes, however Larmor equation would dismiss (I think) efficient ions's radiation from it.

Physics books explain EM wave reflections saying low energy EM photons can transfer its energy to electrons, and they inmediatily return this energy at the same frequencies (they not become "excited"), then I think that a possible explanatory mechanism is that radiating charges in electrolyte be simply the not free electrons (not heavy ions) vibrations induced by electric field in electrolite.

I do not quite trust in NEC optimistic results I got, because I do not know if resistivity model includes electrolytic conductors, but this it is only my ignorance about it, not an sustented opinion.

try modeling it without the ground on the far end and see how much
different it is.  my bet is that it would be much better on some
frequencies and not any worse performing on most others, though the
impedance may make bigger swings.

electric fields intensities because its larger mass. We need higher
electric fields intensities to get accelerations capable of radiating
equivalent power obtained from electrons with lower E fields, then I
believe they are not responsibles of useful possible EM radiation in
our conditions.

Stream of salt water is like a mast made of insulator with its surface
sokaked with the salt water.
It is in state of permanent surface breakdown. So the electrons can flow and
the "mast" works like a metal antenna.
```

I don't see what this in response to (no quoted material) so I will
wing it with an observation.

Building a ground field (like radials, but more linear for dipoles, or
in this case a loop) as a mat will increase performance (more signal
out).

 Richard,
Did you look at #30 in the site index given?
That was the first reference to a "Half Delta Loop" I found. It uses
a ground at the feed point and at the 'far end'. Using a single
conductor to connect those two 'grounds' is a fairly common method of
modifying that antenna. I would have to guess that it isn't the -
only- such modification though.

Hi Doc,

Without quote support for that site, I haven't a clue.

Using a ground at the feed point says nothing, really. What does "ground" mean? A rod? A screen? A radial field? Any of these will change the picture considerably (OK, maybe 1dB - sometimes ground is over-rated).

Here's the original post.

Anybody have experience with the "half delta loop" as shown here:
  http://www.qsl.net/va3iul/Antenna/Wire%20Antennas%20for%20Ham%20Radio
Wire_antennas_for_ham_radio.htm ?
  I modeled it in EZNEC and it seems to solve my space and support
problems on 80/75, and is decent on 40.  Patterns get kinda weird on
20M and above.

Hmmm, Doc is right. Try it an see (seeing there was no ask for how
design variations would impact performance).

I am wondering if anyone has used an elevated screwdriver and elevated radials? I wish to put this up at 22 ft. Above the garden. With at least 1/10 wave radials at 40 meters. Any suggestions?

Wing

Hi all...

I've got one of these "squid pole" telescopic fibreglass fishing poles that I presently use for supporting a vertical 20m dipole. Being the highest point on the property, I thought if I could build a nice lightweight antenna to go high up the top of it, it'd work well as a mast for a 2m antenna.

I'm looking for a lightweight antenna, and feedline, suitable for this purpose. I wish to operate around 144.300MHz USB... so horizontal radiation pattern would be better. I get heard perfectly well on a quarter-wave vertical at present, so I think the gain of a loop will be sufficient... but a bit extra height would help a great deal.

The full-wave loop looks almost ideal... nice and simple, apparently good gain over a dipole for an omnidirectional antenna. I have some 300ohm ribbon I can feed it with (RG58 makes the pole bend over... and of course anything low-loss will be unworkable).

The catch is, I'm not sure how to go about impedance matching, with the loop having a theoretical impedance (so I hear) of 100ohms, the ribbon being 300ohms, and a radio that expects 50ohms. I'm not sure how the feedline characteristic impedance will impact on things, being 300ohm... there's no such thing as 50ohm ribbon in the shops AFAIK. I'm not sure this has to match though. The antenna itself though, does need some sort of transformation back to 50ohms.

Giving it some thought... another way to achieve this would be to use two loops in-phase. 100 ohms in parallel with 100 ohms gives 50 ohms. I'm just not certain of the spacing, and how close they'd need to be. I've got the wire cut to make two loops (no idea what gauge... approx 1.5mm diameter solid copper) to a length of 2.08m.

I'd like to know if anyone has an idea how far apart these need to be (vertically) on the pole so that they work together in-phase (or alternatively, 180=B0 out-of-phase... I just swap the connections on one loop... I suspect this will halve the required distance). I could just experiment, but if someone's been there done that, then I'd appreciate their insight.

Regards,
Stuart Longland VK4MSL

One trick I saw on a ham's web site (I can't find the URL sorry) was to make home-made ribbon cable, running conductors through regular spacers. That could be a good option for you simply because you can make it super light-weight, but it also gives you flexibility with the spacing and therefore the impedance.

I'm not qualified to say how loop antennas are normally matched, but I thought that particular idea might be helpful in your case.

Long time no chat! Cheers,

Tom VK7NML

Chapter 17 of the 1962 ARRL Handbook describes how to homebrew
balanced tuners for VHF. I use the 6M version with either a 6M Sterba
curtain or a fullwave 160M loop, works FB. I also built a 2M version
that works well but doesn't get much use as I don't use that band very
much.

Are you intending putting the 2m antenna on top of the pole carrying the
20m vertical dipole? Do you think they might interact?

Not only light weight, but low wind resistance I should think.

The common '300 ohm' TV ribbon is not exactly 300 ohms, or necessarily close to it. You can expect a loss of about 1dB for a 30m run of matched TV ribnon on 2m.

One solution to 'match' the load to the line is a quarter wave transformer... look it up in a handbook or Google for it. It is relatively easy to construct a quarter wave line section of arbitrary impedance on 2m.

At the other end, you are still faced with the challenge of transforming 300 ohm balanced to 50 ohm unbalanced. You could use the combination of a 4:1 half wave balun using coax (50:200) and another quarter wave transformer to 300 ohms.

The thing is that you might not be able to simply design the sections this simply, you may need to make an adjustable impedance transformer of some kind at the tx end. You could home brew a little ATU, or use something like a stub tuner. Even if the TV ribbon operates at VSWR=3, the loss should be acceptable for a 30m run.

This project throws you into the deep end, a project to drive learning about and understanding transmission lines.

There are a lot of different potential solutions, the above is one and others will have other ideas.

Owen

Hi all...

Thanks for the suggestions thus far...

Regarding the tuners in the ARRL handbook... I've got the 1975 edition
here, I'll have a look there.

On Sep 26, 6:47=A0am, Owen Duffy <n...@no.where> wrote:

I think there probably will be some... but hopefully not a serious
problem since only one will be driven at a time. At the moment I've
got a quarter-wave groundplane and a TV-antenna in _very_ close
proximity (about 40mm apart) so surely any interference I get with the
20m vertical will be minor compared to what I (and the TV viewers at
my QTH) already put up with.

Indeed.

Thankfully, I think I'll be lucky if I use more than 10m... 1dB isn't
too bad though, probably better than the equivalent length of RG58.

By the sounds of things... homebrewing a 2m ATU may not seem so silly... I did make an air-core autotransformer for use on HF which I'm able to use to tune a short end-fed vertical (actually, a 6' 27MHz CB whip) quite successfully on 40m... perhaps the same concept will work for VHF. I was hoping though, if I could hook two loops in parallel, that would give me 50 ohms... I guess it'll be time for experimentation.

Yep... A lot of people say "Just buy X brand/Y model antenna"... but I believe in giving the homebrew route a try first. :-) I live to learn.

If you want to learn something, make your experiments simple... and that
means separating your experimental antenna from things that will (and
they surely will) confuse things.
>
...

Firsly, ask yourself it ATU is a common approach, and if not, why not.

Re the unloaded / base loaded 6'whip on 40m , it is unlikely that it is
very efficient, but there is a lesson there, even inefficient antennas
can be used to make contacts... just less of them. Some people use QSOs
as 'proof' that an antenna 'works', whatever 'works' means.

>
> Yep... A lot of people say "Just buy X brand/Y model antenna"... but I

That was what ham radio was about once, a dying part of hobby now.

Some also say "any antenna is better than no antenna at all", but if you
are interested in the technology of antennas, you will do better than
that.

Good luck Stuart

Owen

I doubt a noticeable percentage of amateurs use wire antennas with a
balanced feed for VHF in 2010. The antenna being considered isn't
commonly used so a common approach to matching might not provide the
most appropriate solution.

The problem is Fritz, that the common HF technique of operating the transmission line at high VSWR and transforming the impedance to that which suits the transmitter at the transmitter is less appropriate at VHF due to increased transmission line loss.

At 2m and above, the technique used more often is to use low loss lines operated at low VSWR, save short sections that might form an impedance transformation function.

That is not to say it can't be done other ways.

Omni directional horizontal antennas aren't very popular on 2m except for the odd beacon and mobile station, full wave loops aren't very often the choice in that case anyway. Nevertheless, the project is a vehicle for learning.

Owen

I think you have hit on the solution. For VHF and above the antennas are
usually resonant and the bandwidth is small enough you can match the antenna
at one frequency and the swr will be low across the band. There has been an
improvement in the coax over the years also. The 9913/LMR400 types have
about half the loss at vhf and above as the older rg-8 type.

While it is hard to put up, the G-line may be something to think about at
450 and above if one does want to use something other than coax/hardline.

Most ssb/weak signal stations operate horizontal on vhf. While you may be
able to have some fun with a small antenna, a 5 element or more beam will
surely help. I did make a contact of several hundred miles on 432 with a
1/4 wave vertical on ssb one time, but that was a rare condition. My
rotator for the beam was locked up and the beam was in the wrong direction.
Just tried the vertical for fun and it did make a couple of contacts.

The radials need to be tuned when elevated. If you used 1/10 wave radials, they would have to be loaded to be 1/4 wave electrically, and I wouldn't expect the performance to be near as good as full length 1/4 wave radials. And.. the radials need to be tuned for each frequency you operate. Which usually means multiple elevated radials for each band to be used.
Myself, I would try to use a longer radiator as well, but a screwdriver will work.. A longer radiator would work better.
I had a full size 1/4 ground plane up for a good while.
32 ft radiator with four 32 ft radials. The base of the radiator was at 36 ft, and the radials sloped down at about a 45 degree angle. I built the radiator from an old 5/8 CB antenna that I reinforced with inner tubing and lengthened to 32 ft. It was totally self supporting and require no radials. Pretty light too.
I don't have it up now, but I still have the antenna on the side of the house.
To avoid radials of any real length the best bet is usually to go

```
with some type of loaded half wave design. IE: Cushcraft R5,

Hi Mark,

Of late it seems most questions are of the "drive-by" category with no apparent interest by the OP for responses.

However, I know full well you will engage in dialog - so here goes:

There is no particular virtue in having the radials being resonant on any band of operation IF the entire antenna is being tuned. And such it would be with an elevated screwdriver.

It then becomes something of an academic issue: why not discard the radials and simply think of the elevated Screwdriver operating as a vertical dipole with one end grounded (where the coax rises from below where the shield is attached to suitable ground treatment)? Just sit on the tune button until the ad-hoc VSWR match is found. That's how Screwdrivers are tuned anyway, aren't they?

Well.. Not quite. But I guess it depends how one is feeding it.
Normally it's tuned by varying the number of turns on the loading
coil, which is motor run. I assume he will have the motor control
at the shack. Normally for the lower bands, you would also use
some impedance matching for a better match to coax. But that
coil or whatever, would normally be at the base of the radiator.
He's basically running a normal everyday ground plane, except
that the radiator is short and coil loaded.
So I don't see it as tuning the whole antenna per say. I still think
the radials would need to be resonant to be effective, and also
do a semi decent job of decoupling the feedline.
>

> Screwdrivers are tuned anyway, aren't they?

Humm.. sorta.. But I'd rather have a lower 1/4 wave section to
act as the lower half of the dipole. Or have radials sloping down
at a steep angle to require less room. If it's high enough anyway..
But the usual screwdriver is just shorting out turns in the coil
to adjust. And the impedance matching is usually fixed and
fairly broad banded in operation.
So when you tune the coil to resonance, the match will generally
be good for pretty much the whole band in most cases.
I've never really used a screwdriver, even though I have one sitting
in the garage.. I preferred my plastic bugcatchers so I could
use a higher coil location for more efficiency and better current
distribution.

But what he wants to do, I consider just an everyday ground
plane, except he can vary the coil loading from the shack.
I'd still rather have the full size ground plane myself.
I'm a radio bully.. :) The one I used really worked well for
long hauls on 40 at night. It would smoke my dipoles to DX.
The longer the path, the better it did. The break even point
where the vertical and dipole were about equal was generally
700-800 miles or so. Anything farther, and the vertical got
better. At 1500 miles, usually 2 S units over the dipole..
To VK land, 4 S units over the dipole. The farther you worked,
the better it did vs the dipole.

"I know the S meters are not accurate, but good enough for
A/B comparisons.."
The elevated version at 36 ft and four radials did much better
than the same 32 ft radiator ground mounted with 32 radials.
The improvement elevated was like day and night.
I calculated my four radials at 36 ft were probably about
equal to 60 or so on the ground.

It was very effective for a simple antenna. The only state
side guys that would regularly beat me were either
running bob tail curtains, or yagis's.. They had to be
running multi elements to win. Course, I usually helped
things by running about a KW back in those days.. :)
Don't want to strain anyone's ears over there. :/

Hi Mark,

That was my point about the screwdriver being run as a elevated vertical dipole.

In point of fact, that is how it is designed to work (after a fashion). The bumper mount (or car chassis attachment) is the grounded lower element, then we have a coil of variable length, followed by the upper element with the feed hidden inside the lower element.

I don't see that radials add anything to this. Their radiative contributions all cancel anyway if they are straight out, and they add towards approximating a vertical element if they droop. If, perchance, you wanted short radials (straight out or drooping), then it would only require more inductance to match the capacitive reactance. Push the tune button and walla! (as the french would say), more turns of the coil out there. And for being a sleeve dipole, that coil would be quite high - current distribution would come out in the wash.

So why not just use two screwdriver antennas with each antenna being used as half of the "dipole"? Since Don Johnson was mentioning this being done in the 90's by apartment dwellers, it's obviously been tried before and may even work. It likely won't be the most efficient at getting the most RF out but likely will work.

I note incidentally that homebrew screwdrivers would drastically lower the cost of this experiment.

Sure, you could do this, but there's really not much advantage over a single screwdriver and a fixed element opposite it. Either way, you're basically putting an adjustable inductor in series with the feed. Whether it's symmetric is almost immaterial, especially for a short (relative to wavelength) radiator.

Short antennas look capacitive. Putting in a series L compensates for that, but doesn't do anything about the low resistance at the feedpoint. What most mobile screwdrivers do is put a 4:1 transformer at the feed.. that gets a nominal 12.5 ohms up to 50, the inductance takes care of the reactive component, and you're "good enough".

In fact, it's typically even more clever, the 4:1 transformer has a fair amount of leakage capacitance, so at higher frequencies, it looks more like a 1:1, which works out nicely, since the feedpoint R is closer to 50 ohms with a longer (in terms of wavelength) radiator.

More details and measurements here:
http://home.earthlink.net/~w6rmk/antenna/screwdriver.htm

I think there are better ways to do a space limited antenna.

I have been exploring models of a quarter wave monopole over a set of radials on 80m using NEC4 models.

If my models are valid, and they use 'average ground', the indication is that while it may require a large number of buried radials (>16) before efficiency levels off a bit, similar efficiency can be obtained with just three radials elevated more than 100mm above the soil.

This leaves me wondering why the popularity of extensive fields of buried radials for the lower bands.

Comments?

Owen

because they are easier to install in most cases than raised radials,
unless you get them far enough up to walk under them like i do.

Just thought I'd throw this out there to see if anybody had any ideas... I was recently playing with an 800 to 1000 MHz Log design. It came out quite well in the model. It was showing that it should do about 1 to 1.5 average SWR, with a couple little spikes of 2.0 or so. So I went ahead and built it.

Now I know from past experience, that testing logs is very tricky. Unless you have a phase stable cable right up to the feed point, you can get all kinds of crazy readings. But still, you can usually get the gist of what's going on. So I go to test the actual finished antenna, and across the intended range, it's showing SWR as high as 7 or 8, and the best it goes down to is maybe 3. Totally different than the model. As a test, I went to the NEC model and took off all the UHF elements, and just added one VHF element to the low end... It showed around 155 MHz in the model. I did the same thing on the actual antenna and got 1.1 around 153 MHz. So at that range, it's right on. But I am baffled as to why it is so terrible on the UHF. I tried shorting the back end and not shorting. No real difference.

Any ideas?

Thanks,

Because my vertical is located out in a pasture. Deer, horses, and the tractor will trip over the wires. Even buried, the tractor tires brought some up when I mowed the pasture late this summer, especially when I turned over the radial field.

Paul

I don't think the model is totally valid.. Partially though..
I agree that for a given number of radials used, slightly
elevating off the ground is better than buried.
But I don't agree that a small number of slightly elevated
radials is equal to a large number of buried radials, and
most certainly not equal to the same number of radials
highly elevated. IE: vs 1/4 or 1/2 wave or more up..
Three slightly elevated radials are not sufficient to lower
ground losses down to a low level over mediocre soil.

I always think in terms of wavelength when calculating
the approximate efficiency of an elevated radial set.
For instance, three radials at 1/2 wave up will be pretty
much equal to about 120 on the ground.
Three at 1/4 wave will be equal to about 50-60 on the ground.
Three at 1/8 wave might be equal to 15-20 on the ground.
Three at cigarette pack height will be equal to about twice
as many as actually used at best. "slightly guessing
on that one, but my real world tests seem to pretty much
agree".
So being as the increase is fairly small at such low heights
in wavelength, it is probably practical to just bury them so
people won't trip over them.. :/
If tripping is no issue, then it might be worthwhile to get
the slight edge in performance. But the increase over buried
will be fairly small with them only 100mm up.

Dear Dave D. (no call sign):

I have found it highly desirable with large and smaller HF LPDAs either to decouple at the feed-point or to choke common mode right as the coax leaves the boom to go down the mast. Of course, one could do both. Once you have cleaned the transmission line, you need to attend to the termination at the end of the boom. Your BW is small for a LPDA so design should be straight forward.

Thanks guys... I've never had that problem before. Any tips for what
clamp-on ferrites might work best, or how many? Or the best way to
configure them?

I am interested in the electrical performance rather than trip hazard. Once electrical performance is known, issues like trip hazard, mowing, rock etc can be dealt with for each application scenario.

So, back to the electrical performance, do you have measurement data, or can you refer me to articles that contain sound objective measurement data that would suggest that my NEC4 model is not valid.

If I have modelled the situation correctly, the models suggest that the portion of energy lost in heating the soil drops very rapidly with increase in height from zero to just tens of mm, and with very little change to the pattern distribution.

Owen

PS: I perhaps need to clarify the meaning of 'efficiency' in my post, I mean the total power radiated in the far field in the hemisphere, divided by the power input to the antenna.

Distributed capacitance is the enemy of any multi turn balun, whether in solenoid style (eg Ugly Balun) or toroidal winding. You could however try to exploit the self resonance by placing it in the band you wish to use, then the issue is whether the resonance peak in Zcm is sufficiently wide.

The W2DU style ought have sufficiently low self capacitance to operate below resonance at 800 to 1000MHz. I would look to #61 material suppression sleeves, but it may be that a lossier material works for your application.

I meant also to ask how you dressed the coax away from the feedpoint.

I often see pics of coax tie wrapped to one leg of the transmission line
spine of the LP. Guaranteed to create common mode current.

Yeah, screw up the windom pattern and see how you like it then!  Why
heat the 1:1 so far away, heat it at the antenna, 30ft up, then you
won't be tempted to check the temp!  ROFLOL

Yep, why I don't like windoms ... unless he has discovered a zero point
energy source, his RF IS heating those beads ...

That's the theory behind the Carolina Windom. Whether it actually performs up to expectations is questionable. The marketing hype acknowledges that the 4:1 voltage balun will cause common-mode current on the coax which is expected for off-center-fed dipoles. They seem to assume that the "Isolator" located 20 feet from the dipole feedpoint is an ideal device with an infinite choking impedance. If it were that, the antenna would work exactly as advertised. Unfortunately, there's no such thing as an ideal isolator so we are zeroing in on what is possible in reality and what must remain as marketing hype. From my modeling, it appears that the isolator works well for any frequency where the length of the coax from the feedpoint to the isolator is approximately an odd multiple of 1/4WL. That occurs on 20m and 10m. Unfortunately, my modeling indicates that RF-in-the-shack may be a problem on 40m and I would be tempted to add an ugly balun.

I do not remember Owen, I believe Q 100 was a number for the text
example, calculated Q on 7 MHz for ideal coil was about 400 and
measured real coaxial made coil with a GR-1606 A near 200. at that
time I did not think to use RG6, It is more light than RG58, isn't it?
Seven turns of RG 58 on 63 mm diameter with parallel condenser it was
very light, enough for the purpose, Rokkaku lifted 40 m "syringe"
antenna flied very well.

R, to two layers choke. Well... frankly to me common mode radiation it
is not something I lose sleep, I have not troubles in my shack and I

was not very lucky in all attempts to reduce nasty modern suburban
noise with baluns + chokes + grounded points, so many noisy companies
and neighbors cables around :>(antenna height showed much better
results.

Hi Ralph,

Then the loss is trivial. On 80M the Z should be sufficiently high enough to prevent a large current to develop a node at that point on the line - it remains to be seen if you need another one further down to suppress induced current that would then slide into your shack (you would be complaining of it by now, however).

Even worse than that! A lot will only consider the loss in the transmitted signal of such an antenna, perhaps even call it "trivial." However, the received signal will suffer from exactly the same losses ... while even losing 500 watts of a 1KW signal can be considered "trivial", losing 50% of ones received signal is NOT!

Regards,
JS

3dB is still only 3dB regardless of where it happens in the link budget!!

That depends on the signal to noise ratio. If the signal to noise
ratio remains the same while 50% of one's signal is lost, the dynamic
range of a low-noise HF receiver usually makes up for it. Witness the
Beverage antenna where 99% receive power loss is tolerated: (from
Wikipedia)

"While Beverage antennas have excellent directivity, because they are
close to lossy earth they do not produce absolute gain (typically -20
to -10 dBi). This is rarely a problem, because the antenna is used at
frequencies where there are high levels of atmospheric radio noise."

Cecil,

If a mere loss of 10% drops you too close to the sensitivity threshold of your receiver, your ability to pull out a weak signal just suffered the kiss of death ... 100w on a kw might not even be noticed on the other end ...

Regards,
JS

As a Windom is only likely to be used on the HF bands (and probably
mainly on the lower HF bands), I would have thought that a few dB of
attenuation would have negligible effect on the SNR.

There are "Windom only baluns?"  I thought that was something they just
told the newbies!

Good mornig Richard

You are right my friend, there are not conduction currents, there not displacement currents, there are not electrical and magnetic fields, there are not electric charges neither electrical dipoles in soil and water, just "mismatch" and "discontinuities" (do explain antenna radiation with "mismatch") I wonder why those evil teachers make me spend my time studying those things. Well... now I will return to my science fiction physics books :) :)

73 Miguel

SRI,

As mentioned in several articles, people have used a horizontal loop as an inverted L, or top loaded vertical, by tying the feeders

together at ground level and tuning it against ground. Specifically,
I am interested in knowing personal experiences with a configuration
of using an 80 meter loop on 160 meters, with the loop 35-40 above
ground. Also of interest is how much of a ground plane was
installed. I'm interested in only stateside contacts on 160, not DX.
If you have used such a configuration, I'd like to hear from you
within this newsgroup or directly.

I've been very happy with the performance of my 40 and 80 meter loops
and use a weatherproof rapid disconnect, for 300 ohm or 450 ohm window
line, when storms approach.

Thanks for reading this posting and don't forget the HF swap nets on
40 and 80 meters.

73,

Evan, K9SQG

I'm not too sure that wire wrapped around a magnet would be that great
at picking up electromagnetic waves - honestly.
I could be wrong, but it doesn't make a lot of sense to me really.
removing the magnet would result in better reception, but the length of
the wire in the voice coil probably wouldn't be nearly enough anyway.

Hi Miguel,

There aren't? You have problems.

> just "mismatch" and "discontinuities"

and more problems.

>(do explain antenna
>radiation with "mismatch")

******** Part One of Explanation ********

What about a conductive antenna is matched to an (relatively) unconductive air (or free space for that matter)?

When your RF, conducting down the transmission line, sees the antenna, it finds either a match and continues into the antenna, or finds a mismatch and is reflected (yeah, some cannot accept the concept of reflected power - so let's say that the energy does not cross the interface except by some proportion in degree to the mismatch).

For what RF power/energy that does get into the radiating element, it conducts down to the end of the element - and guess what? - it stops conducting further in that direction.

Strange that this has to be said, being obvious in the first degree.

So, we have the antenna with some characteristic Z - can you put a number to it? We have the surrounding medium with some characteristic Z. They have some integral (meaning a number, integer) relationship. Dare I call it mismatch?

When you look at the current distribution along a half wave dipole, does it not exhibit a standing wave? If there were not a mismatch, where did that come from?

Are you sure that there no thy field emission?

> Strange that this has to be said, being obvious in the first degree.

The field emission is also in the first degree.

> When you look at the current distribution along a half wave dipole,
> does it not exhibit a standing wave?  If there were not a mismatch,
> where did that come from?
```

It the field emision is strong the VSWR is 1 and no standing wave.

Am I right?

Ian,

Ah, the statements in support of mediocrity about.

Yes, there is an element of truth in what you say... but looking at it a little further....

On any bands where the external noise is very much greater than the receiver internal noise, small extra antenna loss will not markedly degrade S/N ratio on receive.

One of the issues when the feedline participates as an antenna condcutor is that its proximity to noise sources (eg the power wiring of a building) may lead to higher receive noise without increasing signal strength, so feedline participation can degrade S/N by that mechanism. You won't see that called out in Carolina Windom adds which claim feedline participation as an advantage.

On the tx side, loss in the antenna system reduces EIRP, and so directly degrades S/N at the other end. So, even on those bands where external noise is very much greater than receiver internal noise, pay attention to antenna efficiency to achieve optimal radiated power to be heard at best S/N.

One of the bogus arguments often trotted out is that efficiency is less important with QRP since there is less power to damage a lossy component. Another view is that if you start out with a transmitter that is 10dB or so behind the average transmitter power being used, then why exacerbate the situation when an even lossier antenna system.

For a once technically based hobby, we do think up some phony rationale.

It is a personal judgement about whether 3dB (mentioned by one poster) or any other number is acceptable in the compromise that is made with all practical antenna systems.

Owen

Your trolley jumped the rails entirely. Mismatch may well serve as a
reason for this too. Consider:
A train traveling 89mph left Cincinnati at 12PM. An airplane flew out
of Denver at 12:10PM going in the same direction. When will they dock
at the same time in Seattle if they are in transit and Daylight
Savings makes its changeover next month?

For complete credit:
What day did the train leave?
What day did the airplane arrive?

John, when are you going to give up on this crystal receiver set of
yours and get a decent receiver?

http://crystalradiosupply.com/contents/media/litz%20special%20edition.jpg

For me, receiving at anywhere near the 0.13 uV receiver threshold is
just too much work. I think they should outlaw any received signal
below 1 uV.

Oh, yes, I quite understand, balls bounce against walls "because walls
are discontinuities" there is a "mismatch in the media" c'est finite,
that's all folks! good "explanation", why to ask more?, why to ask
"why"? (one step back, the explanation was "God").

Good night Richard (it is time for my catechism)
It is my karma... I know... my second name is Ricardo :D

No, this form of question "why to ask more?" it is ironic, in spanish means that "you", not me, do not want to ask more. You stop the questioning in a high level (as in software "high level" meaning) useful descriptive model of the world and refuse to look for the underlying process responsible of that. "Magic" for me it is =3D> PRINT "hello world", because beneath it is asm code for PRINT instruction, more deep it is movement of bits inside the processor, more lower yet it is the electricity. To explain all program operations perhaps we do not need go beyond PRINT statement knowledge, but BASIC it is not the end of the story...

Why do you think only you study boundary conditions...? it is the more conventional form to treat the issue of reflections! All this speech to refute accelerated electrolite charges radiation? Do better shows to us why a ion vibrating due an electric field it is incapable to radiate EM energy. Better yet, shows us that you has replicated the paper's experiment and has got nil results. Until today we have only scholastic rationalizations, not "bench work".

You said: "well... it is not so good as copper conductor, then it is no good for me", that is not science! that is only your tastes :>P You do not want study or analize technical possibilities with your ham fellows, you like quarreling!, hi hi, Be a good boy, dust off your undergraduated Resnick and see Compton thinkings, interesting things happen at the bottom :>)

>Why do you think only you study boundary conditions...?

I have to think about that question for a while. At the risk of translation problems,
1. I don't think only boundary conditions;
2. I don't think I am the only one who studies boundary conditions;
3. Boundary conditions are not incorrect solutions.

> it is the more
>conventional form to treat the issue of reflections! All this speech

Were you looking for an answer that refutes electrolite charges
radiation? Are YOU refuting electrolite charges radiation? Are
electrolite charges radiation the only solution? Is there radiation
if there are no electrolite charges? [You have already skipped past
dielectric lensing which refracts radiation too.]

> Do better shows
>to us why a ion vibrating due an electric field it is incapable to

Why does it have to be nil?

>Until today we have only
>scholastic rationalizations, not "bench work".
>You said: "well... it is not so good as copper conductor, then it is

I really said that? Looks like a bad translation with extra editing.
Maybe if you use my original post with cut-and-paste.

> that is not science! that is only your tastes :>P

>>"Mismatch" it is another magic word
Is this scientific?

> You
>do not want study or analize technical possibilities with your ham
>fellows, you like quarreling!,

Hmmm, your argument sounds like conservative pleas. Look at second
quote above: "more conventional."   I introduce another analytical
perspective and you appeal to old books reciting stale material:

>hi hi, Be a good boy, dust off your
>undergraduated Resnick and see Compton thinkings

Moldy too.

Your question that I long ago responded to was:
>>what other classical process could explain the EM earth reflection?
and you are very disappointed that I did not boringly repeat the SAME
dusty classical process!

Why did you ask?

Darn Cecil, quite peeking!

From the crystal silicon in the semiconductors, to the crystaline structure of the metals ... I just can't get away from the darn crystal radios! And, alas, I am afraid, these days, the sensitivity of my receivers front end far exceeds my hearing ... I was just bragging. You caught me!

But, I can still remember those days when I could pull out a gnats whisper above ... but then, as I remember, there was far less noise then.

Regards,
JS

I have a half-sloper attached to my tower. It is mostly used for 80 meters (but also for 160 and 40 in rare cases). It is attached to the top of the middle section of a 55' crankup tower. The tower has a number coax and other control lines suspended a foot or so outside the tower. I am in the "far suburbs" but 40/80/160 still have more noise that I hoped and I suspect some of the noise is from the neighborhood; there is no specific noise generator that I can detect.

Question: would a coax choke (5 43-material toroids with 5 loops of coax) at the feedpoint of the half-sloper do any good? I am a little confused since the tower (and, I assume, the outside of the coax) is an intentional part of a half-sloper antenna.

At the bottom of the tower, the coax goes underground for about 50' to the rig.

Bill - W2WO

I can't disagree with anything you say. I'm no advocate of the Carolina Windom, and have no plans to use one.

From the point of view of receiving (and causing) interference, allowing the feeder to contribute to the antenna radiation is certainly something which one should be circumspect about. The various comments and explanations (here and elsewhere) indicate that can be a bit of an art to ensure that the radiating common-mode feeder currents are restricted to where they ought to be.

And while, on receive, a bit of 'unnecessary' loss is usually of little consequence on the lower frequencies, losing transmitter power is not something you want to do, on any frequency (if you can avoid it). But, as always, it is often a balance between performance, convenience, and what you are really trying to achieve with your amateur radio station.

There are two sources of common-mode current. A choke at the resonant
dipole feedpoint reduces the common-mode current conducted onto the
outside coax braid. Unfortunately with the tower being a radiator and
the coax tied to the tower, inducted common-mode is the major problem
and difficult to solve. A choke at the antenna feedpoint will have
little effect on inducted common-mode current. I wonder if you are
frying any earthworms along your buried coax? :-)

You're correct that the feedline and/or tower are part of the antenna. What you have is a dipole (not necessarily symmetrical), with one side of the dipole being the half-sloper "antenna" and the other side being the tower and feedline. The feedline has two transmission line conductors, which are the center conductor and the inside of the shield. Whatever current flows out of one must flow into the other. The current going to the half sloper equals the current flowing down the tower and outside of the feedline shield. If you effectively choke the tower and feedline currents, you'll also choke the current to the half sloper.

While you can effectively choke the current on the outside of the feedline (it would probably take two chokes, one at the top and one at the bottom), it won't help your noise situation. Whatever nearby vertically polarized noise might have been picked up by the outside of the coax will still be picked up by the tower. If the problem is vertically polarized local noise, the only solution is probably to go with a fully horizontal antenna with a well-decoupled feedline.

Hi Bill,

That alone should snub common mode currents (into the shack).

What kind of noise?

Hello Roy

I do not saw this post. I do not know how you make the simulation, I
try a similar one changing "Wire Loss" to "User defined" an put there
5 ohm-m.

The "Average gain" results was very bad, as yours, then, thinking of
aspect ratio of IEEE antenna paper (and big masses involved in water
and soil reflections) I modeled it with 300 mm diameter wire. New
Average Gain now was 0.53 =3D -2.65 dB, pretty near values given in
```

paper.

Ita was approximateli correct my procedure on EzNEC? what do you think about results?

Thank you very much in advance.

Miguel LU6ETJ

PD: I will repeat this post in another point of thread becaus this one it is older.

Hello Roy:

Very good and youseful info. Is it possible change the reflecting
angle in that result?

Miguel

The conductivity of sea water is about 5 S/m. This is a resistivity of
0.02 ohm-m, which is the value you should enter as wire loss.

Sorry, I'm not sure what result you mean. You can't change the
reflecting angle -- the angle of reflection is always equal to the angle
of incidence. And the intrinsic impedance of a medium doesn't change
when a wave strikes it, reflects off it, or propagates through it.

I wanted to mean to choose the incident angle for possible anothers
calculations, Sorry I get confussed with translated meaning of angle
in =3D> "Intrinsec Z =3D xxx at ANGLE of xxx deg, I understood as
incidence angle instead of phase angle, here we can not acostumed to
write in that form and I translated bad the meaning.

Today I posted another EZ-NEC question about a simulation of liquid
antenna based in yours, but I did on earlier thread post point, have
you see it?

(Thank for you quick answer)

Intrinsic impedance is a complex number unless the medium is lossless
like free space, so the impedance of ground is complex. A complex number
can be expressed in rectangular form (real and imaginary) or polar form
(magnitude and angle). EZNEC shows the impedance in polar form which
includes an angle. The angle is part of the impedance and has nothing to
do with any field. Many scientific calculators can convert the polar
number into rectangular form if you prefer.

Yes, I posted a response.

Roy Lewallen, W7EL

Sorry, it is not my day, I didn't see this answer neither. Ok, TKS, my
mistake, now I put 1/5 S/m = 0.2 ohms-m (free space simulation, 0,97 m
length, 10 segs) and similar results to bad resistivity but with 50 mm
wire diameter now (0,57). Do you trust in this results?, seems more
optimistics than IEEE paper.

Miguel

Yes, I trust these results. If the IEEE paper agrees with your earlier calculation, I suspect that the author made the same mistake you did.

Oops, I just took another look at your posting. You should put in 0.02,
not 0.2 ohm-m.

Roy Lewallen, W7EL

Thank you for the confirmation. I'll skip the choke for the half-sloper.

I am aware that many hams take a poor view of these antennas. Perhaps I
am a bit lucky because mine seems to meet my minimum requirements ---
especially for transmitting ---
probably because I do not use 80 or 160 very often. (I still need about 25
countries on 80 for 5BDXCC and this is my driver.) I would love to have
a quieter receiving antenna for 80. There is a very interesting scheme in
the
QST I received today; in effect a rotary beam for 80, with variable angle
of reception.

Might, actually, be better to feed the other end of the sloper, bringing
that end as close to the shack as possible, shortening the coax and
dropping out the associated loss, possibly having a favorable effect on
your noise, etc.

Of course the addition of a suitable counterpoise(s) would be necessary
... just a thought ... and, of course, a notable amount of work.

Regards,
JS

Sorry Roy.  I meant that tongue-in-cheek regarding the rough handling
that routinely goes on in newsgroups.  This one's generally pretty
civil.

Where did you get the idea that electrons that are accelerated are a
intrinsic part of the diamagnetic material?
The air is full of particles from the Sun looking for a place on a
diamagnetic material to rest. The size of these particle is such that
a tensile force is applied to a surface and is of the smallest mass
possible so the speed of light can be obtained. The force vectors on
the surface of the radiater is the surface current and the
displacement current which in conjunction supplies acceleration with
spin to generate charge in a straight line projection to counter
gravity.
 Nature loves simplicity does it not?

I might note here that a Trask 4:1 current balun is not a Guanella current 4:1 balun, they have quite different connections. The argument that Trask makes in support of his design on a single core does not apply to the Guanella design.

The key to the answer is in two words in the first sentence of your posting: "immediately adjacent". You're certainly correct that the current can't abruptly drop to zero at the terminator, because of Kirchoff's Current Law. But the current doesn't abruptly end, rather it drops to zero following a sinusoidal distribution curve. It's quite equivalent to a dipole with insulators at both ends and wires beyond that. There's current on the antenna, zero current at the insulators, and some induced current on the wires beyond due to mutual coupling. If the wires beyond are broken by insulators every quarter wavelength or closer, the induced current will be small. But if the wires beyond happen to be close to a half wavelength, the induced current can be quite high. This is almost exactly the situation with transmission lines and chokes, with the chokes acting as somewhat imperfect yet adequate insulators.

Common mode chokes can be made pretty easily to have an impedance of more than 1k ohm. Both modeling and measurement show this is usually adequate in typical installations to drop common mode current to very near zero at the choke location. But you can easily have substantial current a quarter wavelength on either side of it.

You might want to note that to Trask, he thinks it IS a current balun
... since it has the appearance of two 1:1 current baluns used on a
single core, I tend to agree with his take on it.

This core contains four windings, two on each side, they ARE wound to be two 1:1 current (guanella baluns.) The phase of one winding on the floating side is reversed, resulting in balun voltage being additive for that floating winding, alone.

I should note, this is NOT misleading, the terminology clearly defines
this balun as a "HYBRID" balun.

I take that back, he used the term "IMPROVED" here, in my previous study of these type hybrid is used ... sorry, my error ...

Anyone with EZNEC, including the demo program, can easily get the value of intrinsic Z of various media. Just define a Real ground type in any model and enter the ground constants. Then open the Utilities menu and select Ground Info. A wave normal to the ground will reflect exactly as it would from the junction of two transmission lines with one having the impedance of free space (about 377 + j0 ohms) and the other having the ground's impedance. The nature of oblique reflections depend on the polarization of the wave relative to the reflecting plane (the ground), but a reflection always occurs whenever the wave encounters a change in the impedance of the medium, or a "mismatch" as Richard calls it.

My modelling experience is that other things like connection to ground, and open ends to conductors have more influence on the location of a standing wave pattern than typical common mode chokes.

I have created a simple model of a Carolina Windom at 7MHz, assuming that the device at the dipole feedpoint is a 4:1 voltage balun with negligible common mode impedance, the isolater is 1000+j0 (your nomination), and a feedline configuration that demonstrates that the isolator has not caused a minimum in the common mode standing wave pattern at that point.

A pic of the current distribution is at
http://www.vk1od.net/lost/Clip043.png .

Didn't work for this case, the current minimum is about half wave between the isolator (left hand blue square) and the dipole, and the common current entering the shack (right hand blue square) is quite large.

Apologies, there was an error in the model... I hadn't installed the
source properly. I have replaced the pic at
http://www.vk1od.net/lost/Clip043.png . The situation is a little
different, but the isolator does not force a current minimim at its
location, and the common mode current flowing at the shack is large.

Owen

A "4:1 voltage balun with negligible common mode impedance" isn't a common mode choke, and can't be expected to reduce the common mode current at its location. If that's what the Carolina Windom uses, I wouldn't be at all surprised to find in practice what you see in the model.

In no way is a voltage balun a common mode choke or "isolator". When a load is asymmetrical with respect to ground, a voltage balun actually *forces* a common mode current to exist at its insertion point. Forcing equal voltages into unequal impedances results in unequal currents in the two conductors. The difference between the two is the common mode current. That's why I've tried for a very long time (at least since the publication of my balun article in 1985) to educate people that voltage baluns are not the things to use in antenna systems.

My comments were strictly regarding the properties and uses of common mode chokes (current baluns), not voltage baluns.

The source is actually
http://www.saunalahti.fi/hohtola/ham/windom/windom-balun.htm , presented
the the DXZONE front.

Both baluns shown are current baluns, ie devices with a high common mode
impedance.

One of the advantages claimed of the Carolina Windom is the contribution
of feedline radiation.

If that was your objective, you would not employ devices (such as the
current baluns in the referenced article) that reduce the commom mode
feedline current.

Of course, the objective is a specious one. If you wanted to minimise
participation by the feedline as a radiator and pickup (especially noise,
since it is often closer to some noise sources), then you might use an
effective current balun. Indeed, more that one would probably be needed
for an OCF dipole.

Roy,

Nearly everyone I have worked and who used a Carolina Windom was using a commercial antenna, expensive as they are here because they are not made locally.

I don't know what they use for the 'black boxes', the commercial devices are proprietary and they don't disclose parameters... but if the seller promotes feedline common mode contribution to radiation (as they do), then a current balun at the top frustrates that.

The 'design' seems to depend on the lower device (the isolator, presumably a common mode choke) to cut the common mode current off and prevent it flowing towards the shack... in the style of the O/C switch someone mentioned, but as we both note, that is not consistent with basic circuit theory principles (KCL in this case). The NEC model I posted shows that a 1k isolator (common mode choke) is not effective for that purpose.

As I said in an earlier post, feedline radiation is a specious objective... but obviously quite effective sales wise.

Owen

I did find an article on a home brew 'New Carolina Windom' at
http://www.w5fc.org/files/how-to/QRP%20Expressions_version_1.pdf . It uses
a Rutroff 4:1 voltage balun at the off centre dipole feed point, and high
distributed C implementation of a W2DU style current balun for the 'line
isolater' some distance from the dipole feed point (10' for the 40m and up
version).

The article goes on at length about contribution by the 'vertical
radiator'.

Owen

It is obvious, we are talking about different things. External fields always will induce common mode currents in conductors, then it is virtually impossible completely remove it. We will have commond mode currents in our line if our ham neigbourhood turn on his TX or our wife talk near with her celluar phone too.

When I talk about interrupt common mode current with choke I am not thinking in prevent all possibles external induction fields over the section of line isolated with the choke but in interrupt the current flow that would have in this point if not were the device placed. In that sense no puntual devices can avoid induction laws. Also, a good isolator it is a capacitor and always will allow displacement currents.

From electromagnetic point of view the inductor field beyond the isolator or ideal choke it is the same that any other external field. Not work either if as isolating device I installed five meters of optical fiber and a pair of transducers :>)
Do you search for a TL incapable to induce external fields?, then we are not talking about baluns, perhaps we could talk about EM shieding of the TL.
Similar situation if we install a perfect balun and run the TL paralel to the antenna, common mode current not depends.

73

Owen

It is obvious, We are talking about different things. Fields always
will induce common mode currents in conductors, then it is virtually
impossible totally remove it. We also will have commond mode currents
in our line if our ham neigbourhood turn on his TX or our wife talk
near with her celluar phone...
When I (or "we") talk about interrupt common mode current with choke
(or isolator) I am not thinking in prevent all possibles induction
fields over the conductors. The goal is interrupt a current that would
have in a point if the device (choke) it was not there (neither you
hope for ideal behavior, we must be consecuent).
In this sense no puntual devices can avoid induction laws. Also, a
good isolator it is a capacitor and always will allow displacement
currents.

From electromagnetic point of view the inductor field beyond the
isolator it is functionally similar to any other external field. Even
if you install a five meter optical fiber with a pair of trandducers
isolator betewen a line section you can not prevent electromagnetic
coupling. Similar situation if we buy our ideal balun and then we run
our line parallel to antenna :>)

Do you search for a TL incapable to induce external fields?, then we
are not talking about baluns, perhaps we could talk about EM shieding
of the TL.

Hey Richard

I said you, "mismatch" it is a magical word. TL reflected waves also
are explainabe with "mismatch" word. However mismatch it is a name for
a physical phenomena, what is that? When we talk about a traveling
wave reaching the "mismatch" point we can try to explain WHY the
reflection occur. You can talk about electric or magnetic field
collapsing in discontinuity, etc. One step beyond of a magical word
there are another magical words, electricity, magnetism for example,
well that is the matter: to advance in de why's and the how's,
otherwise we had remained in the realm of Newton and Huygens.

Since I don't know how robust the Carolina Windom isolator is, my following statement may or may not apply to the Carolina Windom.

The above problem goes away *if* the choking impedance is high enough to *cause* a common-mode standing-wave current node (minimum) at the choke because the net magnetic field is then near zero on both sides. The same thing happens when a well-designed trap is placed in a dipole. The high impedance of the trap at the parallel resonant frequency causes a standing-wave current node and reflects the forward wave back toward the feedpoint instead of allowing current to flow through it into the rest of the wire. Here's the current distribution on a trapped antenna. Note how the trap impedance causes a standing wave current node at the trap.

Hmmm....
Something odd here!
When current is a constant as would be the impedance of radiation alone I find the impedance to be 50 ohms and a ground wave exists. Thus the question regarding particles at rest on the radiator. Can the particle skin be classified as a "medium" where a mismatch does not exist and where the mismatch which does exist is between the particle layer and the atmosphere?

I calculated the current moment for the model I spoke of earlier, just considering magnitude alone, to get an idea of whether the common mode current was significant. In this case the current moment due to the feedline is just a little greater than that due to the dipole. Just over 50% of the current moment due to the feedline is due to feedline between the isolator and tx.

The conclusions I draw from the model are that:
- the feedline is just a significant in contribution to radiation as the dipole; and
- the isolator does take the downstream feedline out of the picture as suggested by some explanations.

You can try to compare it to those things you mention, but to me, it is chalk and cheese (ie totally different).

Owen

Nobody said the Carolina Windom choke was that robust - just that it
is possible to design a choke with a high enough impedance to cause a
common-mode standing-wave node at the choke.

> Even if it did drive
> common mode current to zero or near zero at that point, that does not
> mean there is no common mode standing wave, just that a node exists at
> that point.

There is a common-mode standing wave on one side of the choke and not
on the other because the very high choking impedance reflects the
common-mode traveling wave on one side of the choke back toward the
source of the forward wave. I took a trapped dipole and dropped a wire
from one end to mininec ground. The standing-wave current is free to
flow through the choke and establish a standing-wave on the other side
- but it doesn't. Here is what a robust isolator is supposed to do to
the common-mode standing-wave current.

http://www.w5dxp.com/trapgnd.JPG

Again, I am not saying the Carolina Windom isolator is that good -
just demonstrating a principle that you seem to be missing above.

Here's a model of a Carolina Windom on 20m with a 2k choke (isolator)
20 feet down the coax from the antenna feedpoint at a height of 50
feet. The maximum current on the coax braid above the isolator is 0.72
amps. The maximum current on the coax braid below the isolator is 0.14
amps. The radiation pattern is close to the advertised one for 20m.

Now we have to choose: Galiean relativity or Special relativity and,
Stokes ether or Maxwell-Lorentz-Einstein ether.

It seems to me that in you opinion the both: Galileo and Stokes were wrong.
In may opinion the MGX proved that the both were right.

intrinsic part of the diamagnetic material?

In the clouds are electrons. We assume that they are on the surface of the
droplets. But they jump between the droplets.
So the skin effect or your surface current is possible.

>The air is full of particles from the Sun looking for a place on a
diamagnetic material to rest. The size of these particle is such that
a tensile force is applied to a surface and is of the smallest mass
possible so the speed of light can be obtained. The force vectors on
the surface of the radiater is the surface current and the
displacement current which in conjunction supplies acceleration with
spin to generate charge in a straight line projection to counter
gravity.
 Nature loves simplicity does it not?

Nature yes but the teachers not.
You also use many the teacher terms (vectors and so on).

Do not you heard about the kids telephone?
The two cans and the wire. The ions in the wire are the medium for the
acoustic waves.
For the electric waves the medium are the electrons.

The same is with the Sun. The bumps on the surface we see after 8 min. The
auroras after a few days.

Hello,

A large loop does receive more signal, but will also receive more noise/interference. You should optimize for best signal to noise ratio. Often, larger does not mean better.

When you make a loop as large as your room, the wire may run close to mains wiring or equipment that generates interference (that may result in bad reception).   You can better make a small portable loop that you can move around to find the sweet spot/orientation for best reception. You can use whatever insulated copper wire to make the loop.

Best regards,

```

Hello Miguel,

I didn't follow this topic for some days.

The two-step approach will work and you are right, "balun" is not a good word for an OCF dipole as a "balun" can also be a center-tapped transformer where the center is connected to the ground of the unbalanced side (voltage type balun). This one will not suppress common mode current in an OCF application.

What you need is a "device" that does the required impedance transformation and accepts large common mode voltage at the high impedance side without introducing common mode current in the feed line.

Regarding the two-step approach, I have a simple "device" for reception. It consists of a 1:3 (1:9 impedance ratio) ferrite auto-transformer (no galvanic insulation). The 50 Ohms side (coaxial) contains a three section common mode choke to avoid common mode current in the 50 Ohms feed line.

Best regards,

Wim

I think that the simple explanation why 'ununs' get misnamed as baluns' is that, in their wound transformer form, they often look very similar. It doesn't help that, depending on how it is wound and connected, one transformer can sometimes be connected to serve either as a balun or an unun - and, in many cases, also an impedance transformer.

As far as I'm concerned, while I've known the term 'balun' essentially 'for ever', I had never come across the newly-coined 'unun' until fairly recently. It was probably simply known by its function, ie an 'RF transformer'. I have to confess that I don't know why 'unun' has become popular. It's a rather 'ugly' word, and is somewhat difficult to say clearly. Maybe that's why they get mis-called 'baluns'!

There is absolutely no reason why there should be any real confusion between a 'balun' and an 'unun' (other than carelessness, or ignorance of their function). If you want to group them together, they should probably come under a general heading of "RF Transformers, and RF Matching and Other RF Interface Devices" (or maybe something even more long-winded).

Hello boys (greteengs Wimpi, how are you?

For monoband applications we can get more Z from a coaxial choke
making the winding for autorresonance. K1TTT have a good data table.

Time ago I want test differents antenna to lift with a kite and I
found =>
http://www.io.com/~n5fc/rfd.htm, the idea seems to me interesting
enough to make some test that are descibed here =>

http://www.solred.com.ar/lu6etj/tecnicos/jeringa/la_jeringa_revisada-en.htm from here I think of another use of de "coaxial trap" to get more Z from coaxial winding specially in monoband antennas, I named de critter "The Trap balun" =>

http://www.solred.com.ar/lu6etj/tecnicos/tpabln/trampa_balun-en.htm

4NEC2 simulations and real field test show me both approachs works fine :>)

How did you arrive at the value of Q (=100) used in the modelling. Was it
measured, or guessed?

Based on some experimental work, I expect that the effective RF
resistance of a closed space solenoidal coil of braided coax is much
higher than the same straight length a copper cylinder.

BTW, if you want to make a more compact self resonant trap on the lower
HF bands, wind the coil in two layers. The article at
http://vk1od.net/antenna/7MDipole/7MDipole.htm shows a pic of a two layer
7MHz self resonant balun made with IIRC about 6 turns per layer of RG6.

Owen

Good idea. Choose your favorite band for your Carolina Windom and wind an "ugly balun" choke just below the isolator. An "ugly balun" choke is capable of forcing a common-mode standing-wave current node (minimum) on the outside of a coax braid just like a trap is capable of such on a trapped dipole.

OK, I'll ask, "I am correct in thinking that most are using a 'voltage balun' (ruthroff 1:4) as the 'Low Loss Matching Transformer' and a 'current balun' (guanella 1:1) as the 'Special-High Isolation Line Isolator?'"

I mean, logic dictates this to be the best combination ... however, one is best to ask ...

Regards,
JS

Water/Air
Most people would agree that both are physical.

>When we talk about a traveling

>wave

Hi Miguel,

Who is "we?" "Traveling Waves" have their own special meaning, and that meaning is unnecessary for this discussion.

> reaching the "mismatch" point we

We?

>can try to explain WHY the
>reflection occur.

If you choose, but the WHY is unnecessary too.

Skip the magic words, as you call them. Everything you discuss is available, by parts, but together nothing changes anything.

A transmission line is an artificial medium. It is artificial in the sense of being man-made. Being artificial, it attempts to be similar to nature's available media. The electronics is same for all. Discontinuities, interfaces, abound in both artificial realms and natural realms. Their behavior is governed by the same physics - only the parameters are different (which is the nature of reality).

That is what I am using on a home built version. Using a 4:1 voltage balun at the feedpoint and the ferrite bead type about 20 feet down from the feedpoint.

The ferrite choke is doing something as it gets warm while running around about 1 KW to the antenna. Doesn't heat up when going into a dummy load.

My 'Windom' usually works beter than an 80 meter dipole on 80 meters plus gives me the option to operate several other bands.

Sounds like you must be using A LOT of beads for 80m.  Why not a couple
#43 toroids, stacked?  Or, a t300-X or t400-X?

Regards,
JS

Hi Ralph,

Through the 4:1? Probably not, or you would have said so (and unlikely you have gone to the trouble to build a 4:1 dummy load).

As the dummy load is most likely enclosed and shielded, then that suppresses common mode currents due to your test transmission.

And, yes, when your ferrite choke (AKA 1:1 BalUn) heats up that is due to common mode currents that were not snubbed by the voltage balun (by design - so why choose it?).

Add a second ferrite choke (AKA 1:1 BalUn) at the feedpoint -before feeding the voltage balun.

Better in what sense?

no, galileo was right, stokes was wrong.  but you might want to join
that anti-galileo group, i think you would fit right in.

One example that's fairly easy to build. You will need a variable cap for tuning. I don't know what type of antenna you have on the stereo, but one of those loops can be fed passively just orienting it close to the loop or loopstick on the stereo.
If it has no antenna, but connections for an AM antenna, you can using the coupling loop built into the loop antenna, and run coax or whatever to the stereo.

I am not surprised at your results with a dummy load. If it is a well screened unbalanced dummy load, you should expect zero dissipation in the balun cores.

The fact the balun cores are heating in the antenna scenario indicates there is some common mode current. You probably have no idea of the current.

Something to keep in mind is that the average power of uncomressed voice SSB is about 3% of PEP, so if your 1kW was uncompressed voice SSB, the average transmitter power might be more like 30W, or half that in a 50:50 over scenario over the long term.

Another thing is the ferrite toroids heat and cool very slowly, so the operating temperature might still be rising half an hour after the transmitter is applied (so long as you haven't exceeded their Curie temperature).

It would not surprise me if the common mode choke consumes a significant portion of transmitter power on some bands, the portion will depend a lot on your own scenario.

Owen

I found the problem !!! I have just been twisting wire connections so
it takes time to bed in and lower the resistance. I probably will have
to solder connections before the snow flies so the impedance stays
steady and constant. Next job is to determine how high the frequency
goes before
the impedance or something else goes wobbly.

I haven't got the equipment to go very high so I may just zero in on
some satellites to see what happens.

I tested the bead choke just by going from the amplifier to the dummy load. I did not have the 4:1 balun in the line with the dummy load. The dummy load was 50 ohms. I just ran this test to make sure the beads were heating up and not the coax. It is a comercial bead choke and the coax was about the size of rg-58. Suspose to be some kind of higher power rated coax good for over 1 KW. I just wanted to make sure it was power on the outside of the coax and not inside the coax. If inside the coax, then it would have heated up while going into the dummy load as has been mentioned by this thread.

The 80 meter dipole and the 'Windom' are at right angles to each other suported on the ends at 50 to 60 feet. In almost all cases the signals are usually much beter on the Windom. It seems the only time the dipole is beter is when the stations are almost off the end of the Windom. Stations around 45 deg to both antennas still give the windom a beter signal.

I was running the amp around 1 KW with a carrier so the power was a constant KW.
I only felt the choke while testing on 80 meters. It got warm, but not hot after about 5 minuits of applied power while hooked to the antenna. Never got even warm just going into the dummy load.

While I don't know what the choke actually does to the outgoing signal, my reasoning was to try and keep the unradiated power from comming back in the the shack and causing problems.

To state it a bit more clearly - who can make a living based upon their stand on what's real? That always separates the wheat from the chaff.

Mr B, Art, Doctor Smith, how'r you all doin' in the antenna consulting and/or sales and design business?

I expect very well considering you know more than the rest of group that hangs out here.

Please insert ill considered response 6 lines below.

tom

Yes, Art, the above is a demonstration of what you are pointing out ...
how can you possibly think I can miss it?  Can anyone?

When a president like clinton, bush or obama can make president, what
would possibly shock/confuse anyone about this?

Regards,
JS

Hello Roy, good day.

I prefer not use "my" definition or "your" definition words because in this case -at least- I am not the "definer", I only learnt that definition. Anyway, a definition it is not neccesarily a "true", you can define a gnome or a dragon, both inexistent or "untrue" critters (I am not absolutely sure about its "inexistence", hi hi). A definition may be simply the conventional meaning of a term, true or false it is not applicable to it, different logical thing it is a "proposition".

Well, long time ago I learnt a definition of balanced circuit, that definition not mention simmetrical driving to the circuit, only impedance respect to ground. Citation =3D>

Balanced circuits: "The pad in fig 133 it is a balanced circuit (or balanced pad) because there is the same impedance in each line wire. A properly constructed open wire line or toll cable is also a balanced circuit."

(From "Fundamentals of telephony", by Arthur Lemuel Albert, McGraw Hill, 1943, page 265).

I know Wikipedia it is not authoritative but in "Balanced Line" says:

"In telecommunications and professional audio, a balanced line or balanced signal pair is a transmission line consisting of two conductors of the same type, each of which have equal impedances along their lengths and equal impedances to ground and to other circuits. [1]"

Searchiing the Web for definitions I found an interesting article in that item with similar concepts
http://www.multimediamanufacturer.com/articles/whitlock407.pdf
Can you acces to an IEEE definition? I could not.

I believe original definition perhaps was related only to noise pick up in lines, I understand your point and not oppose to it, it is a good point, perhaps we have to say "an all (o totally) balanced SYSTEM" when we want to refer to both (signal and impedance) simmetries, to eliminate ambiguities.
......
Although this is a more important issue, I insist in my original point, is it "licit" to call "balun" a device connected to two unbalanced circuits (line and antenna)?, Is it Carolina windom a balanced antenna?
Here most of hams tend to call balun any toroidal transformer, with TL or traditional windings connected to any circuit! :>)

What you say? Thank for your interest and answers. Best regards to you and all friends.

Miguel LU6ETJ

Actually, balun = "balanced-to-unbalanced", and unun =
"unbalanced-to-unbalanced." I believe that is correct.

And, I am in agreement, I see isolation RF transformers, RF
auto-transformers and transmission-line-transformers and UNUNs' all
grouped together under "balun." It would be nice to have standardized
terminology and everyone is encouraged to use it ...

Other than that, the rest of your post is sure to fire debate, assuming
that everyone even recognizes the above ...

Regards,
JS

Hello all

OK, this probabily is near a joke or hoax, but what about liquid/ionic/dielectric in general? I have a pair of interesting links about it =3D>

http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=3D1461138
http://xa.yimg.com/kq/groups/15085895/1136140553/name/Trees_Antennas_IEEE.p=
df

Time ago I had some doubts about the mobility of ions in a liquid to radiate and calculate how much an electron actually moves when the antenna is radiating to use as a starting point.
The numbers (if I do not make mistakes) showed me to a current density in the order of 5 A/mm^2, free electrons can take a trip of just one three thousandth mm of copper ion radius, surprising result!, really I did not expect such a small value ..., It showed me that electrons in antenna barely vibrate around their resting place when radiates (I made calculations for a irradiant at 80 m).
This favored hypothesis of liquid antenna possibilities because would suffice for the ions (charges) of the liquid vibrate slightly around their points of rest to act as radiators (I do not to solve issues related + ion mass to best "close" my questions).

We know sea water an earth EM wave reflections really are reirradiation of EM energy, then, ionic antennas there are real things, are there? However I haven not study the efficience of this process.

What do you think about it?

Best regards

Miguel LU6ETJ

As you get older, you are slow to call anything "impossible." Many, many things which were accepted as "impossible" as a teenager, are now done daily as I am an old adult ...

However, unless there are some really unique methods
discovered/found/invented/etc. for the manipulation of physics involving
seawater and RF, a "seawater antenna" still remains in the realm of
"impossible", for now ... at least for me ... and by that, I mean taking
sanity into consideration ...

Hi Miguel,

This reference is much better than your first citation - it mentions what the common (earth, ground, other circuits) is, which is necessary for symmetry AND balance. Your first citation merely described a loop. A loop is symmetrical within its own self, but that doesn't make it balanced.

>Searchiing the Web for definitions I found an interesting article in
>that item with similar concepts
>http://www.multimediamanufacturer.com/articles/whitlock407.pdf

This link gives a good introduction to common mode which is central to the problems of balance and symmetry.

>Can you acces to an IEEE definition? I could not.

No point in that.

>I believe original definition perhaps was related only to noise pick
>up in lines, I understand your point and not oppose to it, it is a
>good point, perhaps we have to say "an all (o totally) balanced

No, that is not complete.

>......
>Although this is a more important issue, I insist in my original
>point, is it "licit" to call "balun" a device connected to two
>unbalanced circuits (line and antenna)?,

The word properly formed is BalUn - balance/unbalanced transformer. Similarly you have a BalBal, and an UnUn so that other topologies are properly termed.

>Is it Carolina windom a
>balanced antenna?

No.

>Here most of hams tend to call balun any toroidal transformer, with TL
>or traditional windings connected to any circuit! :>)

The term was not coined through a democratic vote - they are wrong.

Hi Miguel,

Let's see, half the power lost to the antenna:

"A simple monopole antenna was constructed and its reflected impedance and radiation efficiency measured for salt solutions of 2 conductivities and 2 monopole diameters. Two antennas were constructed, 25 mm and 50 mm in diameter, with salt solution at 35 ppt and 70 ppt. The resonant frequency was found to be inversely proportional to salt solution column height, with bandwidths of ?1 GHz (-10 dB S11 points) at 1.3 GHz."

A quarterwave monopole @1.3GHz would be 5.8cM tall and up to 5cM in diameter? A mylar balloon filled with air (not water) wouldn't lose half the power applied. Voila! Wide band, 3dB gain, lighter, and can be made into any shape.

>http://xa.yimg.com/kq/groups/15085895/1136140553/name/Trees_Antennas_IEEE.pdf

This has been a topic here going back at least 15 years.

>Time ago I had some doubts about the mobility of ions in a liquid to

>related + ion mass to best "close" my questions).

Consider a dielectric lens antenna. How much mobility there?

>We know sea water an earth EM wave reflections really are
>reirradiation of EM energy,

This reflection is a function of a severe mismatch between two poor
conductors. You don't need sea water to achieve the same thing.

>What do you think about it?

Hello dear Richard, how are you? I hope very well with yours:

Mylar conductive ballon replacement it is not a valid refutation for
the hipotesis analized, that antenna was only a "test antenna", any
liquid antenna can be replaced by a metalic antenna...! what prove
that?

I was not be here fifty year ago :>) (I suppose "ether" also must have been treated in this newsgropup a hundred years ago :>D) what you think about it (trees) at that time?

I do not know lens dielectric antennas, I learnt radiation it due accelerating charges, electrons are charges, free ions also, non free dielectric charges (E field induced dipoles) too; alternating electric field applied to them produce movement on them, then acceleration, then =3D> radiation. Am I wrong? (yes I know, loss too sometimes).

You say: "This reflection is a function of a severe mismatch between two poor
conductors. You don't need sea water to achieve the same thing"

What "two" conductors? you know air not work as a "conductor" in this analitic environment, it would the same it there were empty vacuum, reflecting medium properties are responsibles for earth reflections.

"Mismatch" it is another magic word, improper of you indeed my friend!, not an explanation :>)
Classic EM radiation (or the same "re-irradiation") it sometimes explained due accelarating charges, and YES, I agree with you, certainly "you do not need sea water to achieve the same thing", you can do it with any other vibrating charge, sea water charges it is only one possibility, conductors, soil substances are other familiar things capable to do it.
We know waves are reflected to ionosphere by those mediums, we can explain that reflections with incident electromagnetic fields and earth surface induced currents; however, "current" not implies here free electrons traveling miles inside a conductor, we have a "current" with any little induced movement on a charge and if this movemente is not constant we have acceleration then =3D> EM radiation, what other classical process could explain the EM earth reflection? I do not know.

However I am not supporting practical liquid antennas here, I have not made the experience and I have not theoretical enough knowledge neither to prove or refute the hipotesis without much more working, I only have some pointers to think over about it.

73

Hi friends

Well... I believe we mostly agree for our internal use, but, there are
a authoritative formal definition? because I do not found it, the only
ones I found were about impedance balance, not signal implied, however
it results strange to me because telegraph and phone lines crosstalks
depend on current balance in wires too, then I think old engineers
should be taken into account, my old RF and telephony books tends to
not use balance word but "symmetry".

I haven not problem with your/our concept, but have we power enough to
become "The Definitors"

Why "do not point in that" Richard you do not trust in IEEE guys? :>)

Miguel

Miguel,

Sometimes the language we use doesn't well describe the thing we are thinking about, and this is a case.

We could well apply a meaning to balanced, that either the currents are equal in magnitude but opposite in phase; or that the voltages wrt some sensible accessible reference are equal in magnitude but opposite in phase. One does not imply the other without constraining the load characteristic.

When we speak of unbalanced, we commonly think of a configuration where one side is 'grounded' and the other 'active'.

The problem is that many situations in antenna systems are not purely either, they are not balanced by one or other of the meanings above, and they are not unbalanced by the meaning above.

So, they need to be dealt with by the more general method of considering that there are non-zero common mode and differential voltages and currents.

It would be most unlikely that a Carolina Windown would be balanced, or near to it, by any defintion. The antenna is born out of a quest to sell the disadvantage of Windom feedline radiation as a positive feature.

The way I like to explain a balun is that it *facilitates* connection of a not-balanced device to a balanced device. A practical balun does not, of itself, eliminate (meaning make zero) common mode current or common mode voltage... yet we commonly use absolute words to describe its action.

To a certain extent, that is saying that they are not ideal or perfect devices. Some of the rules we hams have made for baluns pretty much assure mediocre performance. Like for example what I refer to as Rule 500, that the minimum choking impedance of a current balun is ten times the differential characteristic impedance (commonly 50, hence Rule 500).

I know English is not your first language, but be wary of applying the meaning of words absolutely.

Owen

Hi Miguel,

What does it prove? What does water prove? That it is a poor replacement? Yes.

>I do not know lens dielectric antennas, I learnt radiation it due
>accelerating charges,

That repeated epithet is rather too simple. An electron is always accelerating. A circular orbit guarantees that.

>electrons are charges, free ions also, non free
>dielectric charges (E field induced dipoles) too; alternating electric
>field applied to them produce movement on them, then acceleration,
>then => radiation. Am I wrong? (yes I know, loss too sometimes).

Does swinging a battery around produce radiation?

>You say: "This reflection is a function of a severe mismatch between
>two poor
>conductors. You don't need sea water to achieve the same thing"
>
>What "two" conductors?

POOR conductors.

>you know air not work as a "conductor" in this
>analitic environment,

Right, it is a very poor conductor (and, yet, we still see lightning conducting through it on a summer evening - all a matter of degree).

>it would the same it there were empty vacuum,
>reflecting medium properties are responsibles for earth reflections.

I suppose so.

>"Mismatch" it is another magic word, improper of you indeed my
>friend!, not an explanation :>)

Magic happens.

>Classic EM radiation (or the same "re-irradiation") it sometimes
>explained due accelarating charges, and YES, I agree with you,
>certainly "you do not need sea water to achieve the same thing", you

So then, classic EM radiation is pretty common, and has lost its magic.

Mismatch.

Ever hear a flame speaker? No magnets, no cone, just a flame and an amplifier feeding two probes and *sound* comes out. No one builds them either.

Hello Owen, it is a pleasure to meet you again.

Oh, yes, of course here we use our words with freedom too. I confess I call "baluncitos" (little baluns) the little toroid transformers, specially binocular ones, but in this newsgroup a lot of good people is very strict with wording and precision of terms :>) then I thought it was no exaggeration from me ask whether it is correct use the term "balun" when both sides are "un", hi hi.

However certainly many times in our hobby words are a true trap for novice (and not so novices), then, why not to call things with more proper name?, if a balun do not "baluning", well... call them "seudo-balun" or another similar pointer to true behaviour (as our known "pseudo-Brewster angle"). There is not a languages translation issue here Owen, you and we, in english and spanish, missuse the same words and concepts, the "thing" it is "globalized".
I am far of being a purist of the tongues, but you know, we hams have misleading words, a majority of you are true experts in RF and it is difficult you can become confussed. Anyway, is not something to worry so much either, the mine It was a casual comment, blame to Roy by take us to the hard theory :D :D

Greetings

Miguel

The answer to your question about a Carolina Windom is yes. The answer
is also no. It all depends on what you mean by "balanced". You shouldn't
have any trouble finding an authoritative source to justify either answer.

I have no interest in establishing or arguing about an "official"
definition of "balanced". What I'm trying to do is force people to
define what they mean when they start talking about whether a balun

achieves "balance" in some particular system, or whether some antenna is more or less "balanced" than another. As I hope you've seen, the conclusions can be very different depending on what you're trying to achieve by establishing "balance". In my article I pointed out that achieving "balance" of feedline conductor voltages relative to the Earth or some chosen "ground" point can often *cause* feedline currents to be other than equal and opposite, and therefore make the feedline radiate.

Until you clearly define exactly what you mean by "balance", discussions about it are useless because it means so many different things.

Roy Lewallen, W7EL

-- Be careful with the English language, in which fat chance and slim chance mean the same thing, a wise man is admired and wise guy shunned, and a bag lady and bag man are very different in ways other than just their gender.

I'm far from a language purist -- my vocabulary and standards of diction were largely formed during my military service, which is why my vocabulary is so limited -- in popular company the majority of my literary repertoire is unacceptable and unavailable for use.

But I am big on communication, and really hate to waste my time arguing about senseless things, especially when people can't even rationally formulate what they're arguing about. (That's why I plonked Art, "John Smith", and a few selected others long ago.) Feel free to use words any way you want. But if you use them in an unconventional way (like Art uses "efficiency") or use words with multiple different common meanings (like "balance"), then you won't be communicating but just blowing wind unless you take the trouble to say exactly what you mean. Most people resist doing that because they're not too sure themselves just what they're talking about.

The postings here show that just blowing wind is a very popular pastime for a lot of folks. But it isn't my cup of tea.

Perhaps the term 'common mode choke' works?

I did see a raging argument someone online (eham?) just recently where parties were arguing that a 4:1 Guanella current balun could be wound on a single toroid, it was the way Guanella intended it they said, but they argued that use of two ferrite sticks for such a device was wrong.

In fact, Guanella's article describes his 1:1 balun without any magnetic core material, and the 4:1 balun as a connected pair of 1:1 baluns with no (ie negligible) magnetic coupling. Yet I have seen commercial sites selling a Guanella 4:1 current balun on a single core, arguing that Sevick said it was ok in a certain context... a context that is unlikely to ever exist in an antenna system. But hey, Sevick is Mr Baluns, so they sell. That context relates to another dimension of the balanced / symmetric issue.

Back to the Carolina Windom, a common explanation holds that there is common mode current on the feedline between the dipole feedpoint and the 'isolator'. The notion that common mode current exists on one side of the isolator and not on the other is an interesting one, one better explained by advertising hyperbole than radiocommunications theory.

Owen

The first part, above, implies that no one has ever constructed such a balun(s), one on a single core, one on a dual core, used "balanced" resistances, to serve as loads, then unbalance the loads, and observe results. I have, when constructed properly, one can be constructed on a single core. Is the dual core better? Yes ... is it possible to run the single core balun in conditions where it will fail miserably?; Yes. Is it possible to run the dual core balun in conditions where it will fail miserably?; Yes.

As to the second part, I have found a properly constructed balun to be both, a choke and "impedance-transformer." Indeed, an excellent balun is optimized to take advantage of both phenomenon.

And, of course, I have found and believe a 160m to 10m balun/unun is stretching things, probably beyond what one should (but, hey, you can get by with it), two baluns, a high freq and a low freq are better to cover such a span ... however, you can carry that to an extreme and optimize core material/size and windings for each specific band ...

And, radio is an onion, each layer built on a preceding layer. At the core of all this is the EM transmission theory, and RF is both particles and waves ... obviously, both have great difficulty being true at the same time, so "waves of bullets" becomes the explanation ... obviously, great difficulty is going to be had in having cement solid theory in the outer layers of this onion. By the time you get to "balance" the errors are only magnified ... balance is like any balance in life ... you'll know it when you have it, and benefit from it.

Regards,
JS

I agree with you Roy in several items, when we try communicate with
words and we not share the exact word meanings we end up inmersed in
the Babel course. Moreover, we later build bigger ideas based in that
misunderstood words, then it is not rare that at the end of the
process we can not agree almost nothing.

But there is a problem, explain our concepts writing in a paper it it is not ease too, any dictionary it is circular referenced, verbal or written definitions use words, then such circularity it is inherente to written language in some point we will need to point to an object, event or phenomenom and say to our partner: you see "this is a house", "that is a river". That way we learn languages when we born, linguists call them "ostensive definitions".

Because that, I pointed -in early post- we could end up having to define all words we use. Here we call that process "socratic tests", because a teacher could ask and ask definitions recursively to the extent we were not able to explain even what is a mom.
Also, in some point we need support us in standard accepted definitions of terms with its limitations at risk of failing to have a common language, often authoritative definitions serve to this pupose even although they are incomplete.

I do not would say I hate to waste my time arguing about apparently senseless things because what to me may seems nonsense can be really important and I am not capable to see it, but I agree that comes a point where I tired and renounce (and there are much things that are really suspiciously foolish). However I recognize that drop the bone too early sometimes not conducive to resolving difficult issues, it is all a matter of "balancing" :>)

Thank you very much.

Miguel

PD: Nice examples of english meanings, when we tell: "ese es un hijo de su madre" we are not talking about kinship relationships :>)

How easy it is for you, eh? some day I will catch you in spanish... :>)

Well, it is funny discuss some things with you. (Sorry, I don know how properly quoting with Google, let me use < > for your sentences).

....

Is not that IEEE paper what you called "the Workbench", have done your duties in "The Bench" to refute that paper? :>D

.....

<What does it prove? What does water prove? That it is a poor replacement? Yes>

Certainly "a wooden leg it is a poor replacement for the original one" (Capt. Hooke dixit), but it is better than no leg at all when you do not have money to pay "the million dollar man leg". Science deals with possibilities not with Harvard economists efficientist laws. We, carbonous beings have made of electrolites, open your ham mind, what was about spirit of "to boldly go where no man has gone before"?

....

<That repeated epithet is rather too simple. An electron is always accelerating. A circular orbit guarantees that. >

Time ago you have troubles with this item, until today do you not believes Bohr postulates was intended for atomic orbitals?, do you have forgotten ciclotron radiation?, I talked to you about this curious habit of emmiting waves of circular accelerated charges when we are young.

....

<Does swinging a battery around produce radiation?>

Do you believe?

......

Air a POOR conductor of EM? Oh no! you are not my Clarke, this newsgroup has been infiltered by etherians. They have hi jacked my old newsgroup friend...! (electronic ether, where I read that, before?)

.....

PSE explain me MISMATCH. (I bet that "mismatch" in some point will ends up in Maxwell's Faraday and generalized Ampere law).

73 (so much english for a day to me)

Miguel Ghezzi

The Author do not know about MGX and Stokes. He only know MMX and Sagnac.
Many people do not know the all evidences. Like you.

For such Galileo was wrong. For you Stokes (Chairman of Royal Society) was wrong.

Suppose I buy a roll of thin wires, install multiple hooks at the
corners of my rectangular room, then wrap the wires along the hooks,
then connect the 2 ends of the loops into my hi-fi.

Would that make a great AM antenna? Would it work?

It shouldn't take you more than 15 minutes to try it, and another two
minutes to post what results you got.

If you don't have an old speaker you can use to experiment with, visit
the next local swap meet. I'll be interested in knowing how well it
worked for you.

How about, "I could care less." vs "I couldn't care less."?

From "The IEEE Dictionary": "balun - A network for the transformation
from an unbalanced transmission line or system to a balanced line or
system, or vice versa." They mention the transition from twisted pair
to coax. "Unun" is not in "The IEEE Dictionary".

As you know, common-mode RF obeys the rules of the reflection model. From an (ideal) physics standpoint, there is nothing technically wrong with having zero common mode current between the isolator and the source while having a common mode current maximum (loop) 1/4WL back toward the antenna feedpoint from the isolator. (Assume an ideal isolator with an infinite choking impedance.)

Consider the following example:

Source--------1/2WL coax1--------isolator-------1/2WL coax2----------
antenna feedpoint

The net common-mode current on each side of the (ideal lumped) isolator must be equal to satisfy Kirchhoff. There is no technical reason why the net standing-wave common-mode current could not be zero on each side of the isolator where the isolator is causing a standing-wave current node (minimum). 1/4WL back from the isolator toward the source, there is no technical reason why the net standing-wave common-mode current could not be zero. 1/4WL forward from the isolator toward the antenna, there is no technical reason why the net standing-wave common-mode current could not be at a high (maximum-loop) value. Since it is theoretically possible, one should not dismiss it as "advertising hyperbole" without having performed the measurements to prove that particular statement applies to the Carolina Windom because of poor isolator performance, not because it violates Kirchhoff's laws.

Incidentally, this is the same conceptual error that some folks have made when they reported measuring no phase shift in the current through a large air-core 75m loading coil when installed on a standing-wave antenna. Hint: Pure standing wave current has zero relative phase shift so it obviously cannot be used to measure phase shift. EZNEC confirms that fact.

Yes, it can work quite well, even on 160m!  First, run about ~300 ft. of
wire as high as possible.  Attach the speaker on the far end,
furthermost from the radio.  Go back to shack and adjust the tuner, ENJOY!

Regards,
JS

Good mornig:

I agree with Cecil, Owen, I do not see nothing strange on have common mode current in one part of the line and not in the other, ideal choke it is an open circuit to RF currents.

In Carolina we have at least a pair of possibilities: employ a conventional transformer with pure magnetic coupling (shield betwen windings), then we get Z adaptation and no common mode feed line current or employ another more BW efficient Z transformer with less isolation to common mode current + a common mode choke.

Respect to balancing definitions, I would like to use here a universally agreed definition because we -hams- exchange conceptual and technical information with people of all the world who often study electronics in colleges and universities; seems reasonable to me use a common lenguage. In this newgropup (as others) there are much conceptual and meaning differences, cause that we can not autoreference internally controversial definitions/concepts. I am not a fan of Wikipedia, but its politics to ask for references it is valid and valuable.

>Trees_Antennas_IEEE.pdf

>Time ago I had some doubts about the mobility of ions in a liquid to
radiate and calculate how much an electron actually moves when the
antenna is radiating to use as a starting point.
The numbers (if I do not make mistakes) showed me to a current density
in the order of 5 A/mm^2, free electrons can take a trip of just one
three thousandth mm of copper ion radius, surprising result!, really I
did not expect such a small value ..

In the lattice are the ducts. Not all electrons are in them.

>., It showed me that electrons in
antenna barely vibrate around their resting place when radiates (I
made calculations for a irradiant at 80 m).
This favored hypothesis of liquid antenna possibilities because would
suffice for the ions (charges) of the liquid vibrate slightly around
their points of rest to act as radiators (I do not to solve issues
related + ion mass to best "close" my questions).

Ions in copper vibrate with the acoustic frequencies.

>We know sea water an earth EM wave reflections really are
reirradiation of EM energy, then, ionic antennas there are real
things, are there?

At the higher frequencies the AC conductivity increases.
So there are more electrons.

>However I haven not study the efficience of this
process.

Consider that on the Earth is excess of electrons.

The difficulty with having common mode current on one side of an "isolator" or common mode choke (current balun) is that it creates a field which couples to the line on the other side, generating a common mode current on the other side. This is exactly the same phenomenon that occurs when you put a common mode choke at the feedpoint of a J-pole or ground plane antenna, or for that matter an off-center fed dipole. You end up with near-zero current at the point where the choke is inserted, but an increasing value of common mode current from there downward, peaking at about 1/4 wavelength from the choke and every half wavelength onward. The most practical solution I've found is to insert a second common mode choke about where the first peak would like to be, that is about 1/4 wavelength below the first choke. This forces the common mode current at that point to be near zero, breaking the resonance of the nearest half wavelength of line and putting the susceptible remaining transmission line farther from the radiating portion of the line or antenna. But compromises or additional chokes have to be used if the antenna is operated on multiple bands.

Hi Miguel,

I presume you mean my comment "no point in that."

It simply means (and ties in with the joke above) that the topic requires no authority to bless it.

Symmetry and Balance are always referenced to some third element or characteristic. In our context, it is usually ground. In our context, ground is also called "common."

No one is really interested in Symmetry and Balance unless there is a nearby ground or common.

Many, many posters here can present some very confused postings about balance, what ground is, and what constitutes common mode. You have already revealed that a lot of your fellow Hams in Argentina (and this is not confined to any country) are confused about the purpose, use, design, and need for a BalUn (or BalBal, or UnUn) transformer. Going further, they (speaking of those many, many posters) are also confused about what a "transformer" is - thinking it is equivalent to the iron-core variety.

And on, and on, and on....

Too bad you weren't on the bus I caught from Abasto to Calle Florida
when I had to figure out how much fare I was supposed to put in. My
XYL was laughing at me from the back of the bus as she watched (and
the other passengers waving their hands to indicate I had put in
enough).

> I agree with Cecil, Owen, I do not see nothing strange on have common
> mode current in one part of the line and not in the other, ideal choke
> it is an open circuit to RF currents.

Miguel,

There are two issues.

Firstly, if the common mode choke (or isolator) is physically small with respect to wavelength, and there is common mode current on the line immediately adjacent on one side of it, why is there not an almost equal common mode current on the other side... or explain the current path that allows the first mentioned current AND that complies with Kirchoff's Current Law.

Secondly, the common mode 'conductors' are coupled conductors. I see that Roy has dealt with that, so I will leave it at that.

For these reasons, it is naive to think that a practical common mode choke has such extremely high impedance that the common mode current through the choke is zero, or even near to it. Even if it did drive common mode current to zero or near zero at that point, that does not mean there is no common mode standing wave, just that a node exists at that point.

Ask yourself how whether the use of a common mode choke (isolator) to effectively reduce common mode current between the common mode choke and the tx don't also reduce common mode current between the common mode choke and the dipole feed point.

Owen

Now I'll listen.

People trying to resurrect old and not very plausible theories by equating quantum soup to "aether", or even phlogiston is a great way to dismiss their ideas. Maybe the flat earthers are right too - we just haven't found the right proof yet.

It's all the same, ether (aether), but like all things which some find disgusting, some attempt to play word games, like renaming a rose ...

Another example: homosexual = gay

Stupid if you ask me ...

The last line is telling. If you choose nature over God, you will lose. A lot of people choose religion over science, and apparently always will. To the point where I have heard just this year both that God placed fossils in the earth and that Satan placed fossils within the earth. The former as a test of faith, and the latter as temptation. Though of course why God would put something in as a test of faith by the positive outcome being a rejection of the evidence seems a little strange.

So if people can dismiss actual physical evidence, it is no surprise that they will reject evidence of a more aetheral nature.

It's their right, always important to remember is that we are all going to hell in someone's religion.

Before beginning a discussion about what constitutes a balanced load and what doesn't, how about answering these questions?

1. What is "balance"?
2. What defines a "balanced" feedline?
3. What are the properties of a "balanced" load?
4. How can you tell when a line, load, or transmitter is "balanced"?
5. What's the big deal about being "balanced", anyway?

And finally,

How does a balun achieve "balance"?

Roy Lewallen, W7EL

Tell 'em one thing "balance" means is if you have a funky antenna
depending on feedline currents/radiation/etc. you don't start chucking a
bunch of stuff in the feedline without expecting patterns to change ...

ah, you think because they mention the gps system using the corrections that were detected by the mgx experiment that there must be an aether... but you are wrong, the gps system uses the acceleration corrections predicted by special relativity that were verified by the mgx experiment... there is no aether involved, it is the acceleration caused by the rotating earth that causes the effect. but of course you won't believe that and will insist that it is because of aether dragging, but that would cause many other effects that are NOT observed... in order for a theory to be right it must do 2 things, it must predict something that can be observed, and it must not fail ANY test that would disprove it. all the aether theories have failed at least one test over the years and are therefore incorrect.

What does the rotating earth accelerate? Light, RF? The speed of light
is fixed within its' media, the ether, the only way to accelerate EM is
to accelerate the ether itself ...

The exact same arguments you state can be used as an argument for the
ether as well as SR ...

Actually it is not always summer somewhere.  That's quite obvious.  It
is only summer somewhere 6 months of the year, the other 6 it's spring
and fall.

Hello Roy

Why? that way we can end up having to define all words we use :>). I learnt a two terminal balanced circuit basically have the same impedance respect to ground in its terminals, if Windom Carolina not have it, well... we have missed the "bal" part of the equation :>)

I recognize the other items are interesting to analize too but in diferent sense that the proper use of the term "balun" towards I pointed my little observation.

Years ago I have read your very good article "Baluns: What They Do And How They Do lt" (until today I keep it safe in my computer for reference) and I believe I understand where you point to with the other good questions.

For John: Dear friend I could not translate well your post, may you repeat in a little more Tarzan english for me?

Miguel

Miguel,

I can see why. I used some good old American satire-humor ... it is OK
my friend ...

Suppose you connect a transmission line to a perfectly symmetrical, horizontal antenna. The antenna and feedline would be a "balanced circuit" by your definition, since the two conductors of the transmission line have equal impedances to ground. But the transmission line will radiate.

Now connect one conductor of the transmission line to the center of your rig's coaxial connector, and the other conductor to the rig's chassis. (This is Fig. 2 of the article you mention, which by the way is available at http://eznec.com/Amateur/Articles/Baluns.pdf.) Is it still a "balanced circuit"? Why or why not?

Or suppose you take two signal generators which are perfectly coherent (i.e., phase locked to run at exactly the same frequency) and exactly in phase with each other. Each has a 50 ohm output impedance and each produces exactly 1 volt RMS of RF when open circuited. Connect one of these to each of the terminals of the feedline instead of connecting the feedline to your transmitter.

Now,
-- The impedances to ground looking toward the antenna from the feedline are the same for the two feedline terminals.
-- The impedances looking back toward the generators from the feedline are the the same for the two feedline terminals.
-- The two feedline conductors have equal voltages and currents.
-- The circuit is surely balanced by your definition.

Yet the feedline will radiate. Change the generator phasing any other angle except 180 degrees, and the feedline will radiate. Only when the two generators are exactly out of phase will the line cease radiating. I call that condition "balance" for the reasons explained in the article, but it's quite different from your definition.

If we're to use your definition of "balance", we have to conclude that balanced transmission lines radiate some times and some times they don't. If the system is already "balanced" when the generators are zero or, say, 90 degrees out of phase, would a balun do anything if connected between the generators and transmission line?

> S*

>ah, you think because they mention the gps system using the
corrections that were detected by the mgx experiment that there must
be an aether... but you are wrong, the gps system uses the
acceleration corrections predicted by special relativity that were
verified by the mgx experiment... there is no aether involved, it is
the acceleration caused by the rotating earth that causes the effect.
but of course you won't believe that and will insist that it is
because of aether dragging,

Earth rotate with the soup around the Sun (Sun's ether drag). No the Earth's
ether drag.

> but that would cause many other effects
that are NOT observed... in order for a theory to be right it must do
2 things, it must predict something that can be observed, and it must
not fail ANY test that would disprove it.

Stokes ether not fail ANY test.

> all the aether theories
have failed at least one test over the years and are therefore
incorrect.

The only one ether theory have failed. The solid dielectric ether. That
described by Heaviside:
http://en.wikisource.org/wiki/Electromagnetic_effects_of_a_moving_charge

" It will be understood that I preach the gospel according to my
interpretation of Maxwell, and that any modification his theory of the
dielectric may receive may involve a fresh kind of propagation at present
not in question."

"All disturbances being propagated through the dielectric ether at the speed
of light,"

Now is like Cecil wrote: "Assuming the aether is the same thing as the
quantum soup, EM wave
propagation would not be possible without it. "

The next name is the "Interstllar Medium". The each soup must rotate with
the Sun because it is the Sun's product.

The soup is not the dilectric. It is plasma and as it is a conductor like
metals. Your radio waves propagate in the same manner in the metals and the
soup. They also propagate in a dilectrics as the displacement current.

But of course you won't believe that and will insist that it is because of
SR.

Even if you remove the misc quantum particles empty space isnt nothing. The problem most people have with their concept of the universe is thinking of totally empty space as nothing. Space even completely void of energy and various subatomic particles is still something. We know that something can be altered so if you want to call it Aether go ahead, a rose by any other name.....The present title is usually space/time.

You touched on one major problem there, which throws most people off and keeps them from being able to realize there is an ether, time. There is no such thing as time which you can put in a bottle. There are no time wells, there is no time flow, time is an imaginary concept.

Time is simply movement and distance conceptualized into a singular "thing." No one has ever experienced time, they experience movement and distance. No device has ever been created which can measure time or, even, detect time. Our very best and most technical clock only measures movement and distance, or loss of mass (movement of electrons away from the main mass.)

If you have your mind locked into the space where it still conceptualizes time as a real thing, it is going to be difficult to make the jump in thinking to be able to conceptualize the ether. The ether is what allows a concept like time to look real, a medium for things to move through and required for anything we are seeing happening to occur in.

Regards,
JS

A coil of wire is a poor radiator for the same reason balanced
transmission lines for most all practical purposes do not radiate.

Nope, it's not. Nothing that is completely devoid of energy/matter is
absolute nothing, i.e. zero volume and outside of the boundaries of
our universe, i.e. our space is a property of matter/energy. That
absolute nothing is what allows parallel universes to exist with zero
communications between them. The space contained by our universe is a
bubble caused by matter/energy. Outside that bubble is absolute
nothing.

I don't think so.  We have nothing which can "touch" either, no "bottle"
we can hold some portion of it in ... and a soap bubble can't exist in a
vacuum ... I doubt if an either bubble can exist in "nothing."  At the
very least, there would be yet another undiscovered media which supports
ether in the same manner with our ether supports our matter, and does
interact with ether ... but, that is only using logic.

I seen some news on the hadron collider ... they are moving up the time
frame when a lot of their predictions, on new particles, should be
found/proven ... I forgot to bookmark it.  If I find it in the future I
will post it here ...

Regards,
JS

no, sr is not necessary for propagation.  and a dielectric is not
necessary for displacement current.  nor is plasma necessary.  you are
still very selective in your reading, a simple search shows that
stokes as well as all the other aether theories have been disproved
for nearly 100 years now.

you obviously don't know the difference between speed and velocity and how you can accelerate something without changing its speed. in any case, if there were any kind of aether dragging or acceleration it would cause shock or bow waves of compression in the aether at some point that could be detected by variations in the speed of light in different directions. this applies for earth dragging aether, or mr. b's sun dragged aether.

> ... I doubt if an either bubble can exist in "nothing" ...

That's exactly what I was trying to say. The quantum soup that we call "empty space" within our bounded universe is not empty. Space within our universe can never be absolutely empty and always contains at least dark energy which comprises ~70% of our universe. It is sometimes called zero-point energy, surrounds us, and allows us to exist. From Wikipedia: "Zero-point energy is sometimes used as a synonym for the vacuum energy, an amount of energy associated with the

vacuum of empty space. When the term is used in this way, sometimes it is referred to as the quantum vacuum zero point energy." Absolute-nothing, i.e. less than zero-point energy, is the complete absence of any type of matter and energy. Space cannot exist within absolute-nothing which is what makes parallel universes possible. Instead of asserting that space contains dark (zero-point) energy, it would be more correct to to assert that space is the *result* of the pressure of dark (zero-point) energy, i.e. the quantum vacuum that we call "empty space" is *caused* by the existence of zero point energy left over from the big bang - also responsible for the present expansion of the universe.

has anyone linked zpe or 'quantum soup' or dark energy to
electromagnetic waves in a way that preserves the constancy of the
speed of light in all reference frames? or related those phenomena to
epsilon or mu of free space?

It is so confusing, there are so many, let me see, you are the guy who wants to purchase the bridge I have in brooklyn? Just send me the check; We will go from there! :-)

Regards,
JS

You will go to any complexity, any obfuscation, any devious explanations of enormous proportions ... it is easy to recognise befuddle confusion, it looks just like all that BS.

When you get to the real explanation, it is simple, you will know its' truth by the beauty of its' logic. The creator didn't construct all the other parts of the universe thus, but when he got to the ether decided to make it enormously complex ... you should be ashamed, your IQ is showing ... what is the temperature of this room?

Got cha'. Close enough, I agree, we do agree ... we wear the same hat.
  It is actually platinum foil, those fools over there think it is
tinfoil! ROFLOL

However, only logic and reason dictates the above, which you correctly
posted. If you believe in magic, bullets shoot from our antenna(s)
across an empty void ... and sugar plums dance on the heads of pins.

no, i am the one that uses real science to confuse mr.b and art by
pointing out reality.  i already have enough bridges of my own to
maintain on my property.

Yes, well gather all your self-important BS around you, along with those
you can impress with your cr*p ... and have at it ... I can safely
dismiss you as a malcontent and chit-stirrer.

Frankly, I will give you this, the benefit of the doubt: I am not sure
you are doing it intentionally, you could actually believe it.
None-the-less, it is still what it is ...

Regards,
JS

of course i am doing it intentionally, stirring up art and mr.b is
just pure amusement. their science is pure junk, mr.b has been going
backwards in time for a while now dragging up ancient history that has
been well debunked. art just makes up technobabble based on whatever
he thinks he sees jumping off his antenna that day.

You build your premises on card board with rube goldberg logic and mechanics ... Einstein had to renege and accept the gravitational ether, without it his relativity falls apart ... you waste my time and are given to grandiose delusions ... you can't even recognize the impossibility of your own argument(s.) But, you want me to take it seriously ... I find that, a lot, but around people I usually choose to avoid. Some think homosexual marriage is logical ... I have seen it all.

Regards,
JS

no, you must have me confused with someone else.  i quote well
accepted engineering texts and journals.  its art and mr.b that put
together rube goldberg theories to fit their latest whim.

Yeah, you are like richard clark, you base beliefs and claim facts depending on who states them, and proudly so, it is not the context of the statement, it is who said it, the above is an excellent example, in your own words. A million men can be wrong, just as easily as one ... especially using the your method, above ... an echo chamber is not a place to seek truth.

You probably think 9/11 wasn't an inside job too ...:
http://www.prnewswire.com/news-releases/architects--engineers-for-911-truth-announces-hard-evidence-of-explosive-demolition-of-world-trade-center-high-rises-on-911-102519299.html

There are your experts, engineers architects ...

no, you must have me confused with someone else.  i quote well
accepted engineering texts and journals.  its art and mr.b that put
together rube goldberg theories to fit their latest whim.

The speed of light is measured in length/time, e.g. 186,000 miles/second. Given that relativity affects both length and time in different ways, wouldn't you say that the choice of the speed of light as a universal constant was somewhat arbitrary? Why should a universal constant involve 0.416667% of one rotation of the earth? What did the universe use for a second-of-time reference during the 8? billion years before the earth was formed and started dictating the length of a second? IMO, the universal speed-of-light constant is just an arbitrary reference point that had to be cast in stone before the math would work.

If we stretched a physical cable between our galaxy and a receding galaxy and found that the cable didn't break even though the galaxies were receding, what could we conclude? I have concluded that the red shift is not because the galaxies are receding faster and faster but because the velocity of recession is actually slowing due to gravity. What we perceive as recession contains relativity effects due to decreasing velocity which causes space to expand and seconds to become

shorter. 186,000 miles gets longer and one second get shorter The
resulting length/time calculation is a double whammy red-shift error,
IMO. The universal speed-of-light constant only applies to a lone
observer capable of immense rationalization.

speed of light in all reference frames?

You do not know that the reference frames are dragged:

""Frame Dragging
One of the strangest predictions of the general theory of relativity concerning black holes is called frame dragging. For a rotating black hole, the theory predicts that space and time itself can be dragged by the rotating black hole. The adjacent figure shows an artist's conception of this idea (J. Bergeron, Sky & Telescope: get permission; Ref). Some recent data has been interpreted as supporting evidence for frame dragging around a black hole (Ref). "
From: http://csep10.phys.utk.edu/astr162/lect/blackhole/blackhole.html

If you do not like the Sun's ether drag you can use the Sun's reference frame drag. Which one do you prefer.

> or related those phenomena to epsilon or mu of free space?

The space is not a dielectric. Electric waves travel in metal transmissing lines where no epsilon or mu.

I have always wondered which of the 2 groups debating here are more
successful.  Like who gets paid for their stand on what's real.

Ok, I don't actually wonder.

Yeah.  I guess some stare at their belly buttons for hours, and wonder;
  And, I guess some hold them in high respect as gurus ... I don't.
Good to hear you ain't wonderin'.

Having dealt with water streams for a while, I wonder how the stream
is measured, because all streams break up into droplets at some point
well before they appear to do so.

John
Look at his last 100 posts and check to see if you find one of them
informative and then question why you even respond to him? I mean it.
He sends nothing but trash all the time. Anybody can say "babbling
nonsense" but not anybody can explain
babbling nonsense unless  he himself is well practiced in the art!

You are absolutely correct. Would be interesting to have real time monitoring of the match, field strength in relation to a standard 1/4 wave and real power delivered to the water stream. I am thinking this is the dummies, dummy load. Or, the dummy load of the century ... could sure use a 5KW ferrite core like he has, just sink the signal into a "barrel of saltwater dummy load" ... would be nice to be have this dis-proven and start discussing why.

Who knows, when the stream goes "live" perhaps the feedline "lights up" as a radiator. As someone already pointed out, the repeater makes one highly suspicious. I mean, is he line of sight from the repeater? How far is he from the repeater? Why didn't he just choose direct contact? Etc., etc. He certainly could have supplied us with better.

I just might write him and ask him for a new youtube video and different test parameters.

Regards,
JS

John
After you read his last 100 posts you can now look ahead and predict
what his next 100 posts are going to look like. Do you really need
such a discorse for the next month or so?

I have a "weird thing" about windoms ... I just don't trust an antenna
which "manipulates" RF on the feedline in "beneficial" ways and has a
religious cult following ... insane quirk of mine, really. lol Now I
don't have the room ... moved again.

If the wife had her way, we would move to Montana next to a favorite
sister and brother ... there we would have the room! lol

Let's call it "quantum ether" to distinguish it from the earlier obsolete concepts. Yes, dark energy seems to make up ~70% of the universe which is mostly space so there is little doubt that quantum ether space is related to dark energy in some way.

Just throwing in my comments on the so called Carolina Windom like Cecil
described.
I have one up like that and also an 80 meter dipole and triband beam up to
compare signals with.
Not all cases, but many times the Windom is as good or better than the other
antennas. The beam does beat the Windom by about double the microvolt
signals on the very long signal path.

The balun I am using is suppose to be able to handle the power I am running,
but around 1 kw to the antenna the 4:1 balun overheats after about 5 minuets
and the swr starts going up. There is some current coming down the feedline
as the choke balun 20 feet down the coax is getting warm. It does not do
that with about 1200 watts going into it while connected to a dummy load.

Like most any simple antenna, you throw RF at it and hope the signal goes in
a direction that lets you make contacts. The antenna can be set so that it
is most favorable in one or two directions, but when making contacts all
around, it is difficult to change the direction of the dipole.

I was referring to the feed line. But since you brought up the antenna
I just noticed that it had only a portion of top band when resting on
the ground so I have to check it out on the tower before I move on.
Maybe just lifting it up a couple of feet will do the trick.
Eat your heart out dummy !

magnetic coupling to the stream seems kind of odd, but it appears to
work for him.  i wonder what happens if you go qro?  i would expect
some heating of the water and maybe even some ionization or corona
that might cause instability in the stream.  i would also guess the
tuning would be difficult in high winds.

Hello John,

When the feed line goes to a clean environment (for example a ground provision far from the shack feed line radiation may not be a problem, but it isn't my favorite. When the feed line goes directly to the shack (and equipment), I don't want such an antenna.

When you are working NVIS on 75/80m, you don't want the vertical component as this leads to radiation under low elevation, hence stronger reception of ground based interference.

In case of DX, the vertical component may help you as this may result in lower elevation of main lobe; over here we have much soil with better then average conductivity. If I would like vertical polarization, I prefer 100% of that, so no windom or OCF dipoles for me.

Depending on the design, allowing vertically polarized radiation may result in worse or better VSWR.

Regarding the color, many straight people wear it over here (especially in summer days), so you can't judge on color only....

Regarding the balun/transformer, you need a very good one with OCF dipoles as common mode voltage at feed point can be in the 300V range with 100W input. just some pF stray capacitance in a transformer will provoke feed line radiation.

Best regards,

Wim

If anything is to occur it would be at the toroid which the water is
flowing thru. In this case the
diamagnetic material is the prime mover with respect to toroidal
field.
What the feed line is doing is not mentioned and it could well be the
toroid windings alone is doing all the radiating

Watch the video again. If we can believe that the video has not been manipulated then, the signals are not present until the water flows ...

I seen this done many moons ago with a thick quartz tube(s) and a column of mercury, mercury height varied to tune ... I'll bet the "mercury" antenna is/was immensely more efficient ... the magnetic coupling would be a great aid in NOT having to tune the match constantly ...

Regards,
JS

An HF antenna would need to put up a water stream "about 60 feet."

Hmmm, about 3kPa for each foot of water or about 200kPa. At Walmart, for $320 you can buy a pump with a 2HP motor to do the job:
  230V @ 11.2A

2.5KW to erect the antenna for a 100W HF rig. If you stacked 50 HF rigs (end to end for more length), you would have both the same size antenna, plus ALL of the 2.5KW of power going to RF and not water.

Very interesting indeed.

Wind would seem to be a weak point. The top of the conductive stream would dissipate at different heights depending on the wind velocity, so a gusty wind would be constantly altering the effective antenna length.

Part of the speal given talked about the scarecity of real estate for
the many antennas on ships! Why don't they use non frequency dependent
antennas so antennas can be shared, especially when in combat? And
what do submarines use for antennas
when in the stealth mode?

On 7 MHz a dipole constructed of salt water: Er = 81,
conductivity 5 S/m, and 0.5" diameter has a free
space efficiency of 0.08%. i.e. with 100 W input
the total radiated power = 80 mW.

Antennas which pop up out of the deck plating would be something. That idiot has just developed a very expensive toy ... and a very poor one at that.

Regards,
JS

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)

>of course, but this was not detecting aether movement, it was
detecting acceleration from the rotation of the earth as predicted by
special relativity.

In 1905 Einstein wrote: "Examples of this sort, together with the
unsuccessful attempts to discover any motion of the earth relatively to the
``light medium,'' suggest that the phenomena of electrodynamics as well as
of mechanics possess no properties corresponding to the idea of absolute
rest."

In "1925 - the Michelson-Gale-Pearson experiment produces a positive result"
(motion of the earth relatively to the ``light medium,'')

As you see after 1925 all predictions of SR and EM are the tales used in
schools to teach the math.

Takes a lot more HP to make a free flowing fountain that high.
Jet d'Eau in Geneva is 500 liter/sec with 2 500kW pumps (of course it is
140 meters tall)..(And yes, it is very impressive from a distance..)

The Buckingham fountain in Chicago is shorter (ca 50 meters) and has
much lower power pumps: 75,190 and 250 HP

> 2.5KW to erect the antenna for a 100W HF rig. If you stacked 50 HF

You can recover the energy in the water coming back down. If you have a
tube, you can either just feed the conductive fluid up the tube and fill
it (a sort of liquid SteppIR vertical), or, for fixed height, you could
have a recirculation.

This isn't particularly new or novel, by the way. The idea has been
around for decades (I think I saw some papers from the 60s analyzing
it). What's new is that the surrounding technology might have changed,
and what was impractical back then might be more practical now.

60 feet is not in the league of 140 meters or the shorter 50 meters.

However, to other comments, keeping it a column of water instead of
spray would certainly add to the pump load.

>You can recover the energy in the water coming back down.

leaps and bounds.

>If you have a

Which argues why not fill the tube with a tape measure instead?

>This isn't particularly new or novel, by the way. The idea has been

>and what was impractical back then might be more practical now.

The surrounding technology, literally, is the ferrite ring enclosing
the column. In 1960's dollars, cheaper perhaps but nothing newer. And

cheaper is relative - not particularly affordable.

That looked so bad I had to run an analysis to see for myself. Sure enough, it's that bad. And even with a 0.25 inch diameter column at 146 MHz, the efficiency is only on the order of 1%. A foot and a half of wire vs. a pump, power source, and ferrite transformer? No contest.

no, its positive result was the acceleration caused by the rotation of
the earth, as in the michelson-morley experiment they detected no
motion with respect to a fix or any other aether... otherwise the
result would have had a predictable variation due to time of day or
year, which was not detected.

On the surface, that statement simply sounds insane. It is always noon
on some portion of the planet and it is always summer somewhere ...

Regards,
JS

Naahhh.. everyone knows they drag an insulated wire, which is why NEC
was updated some years ago to handle insulated wires in a conductive medium.

Now.. when their periscope is up, indeed, there's a lot of special stuff
that goes into shared apertures. Look to the work of Jaumann in WWII..

And with sharing apertures.. it's not so much non-frequency dependent
radiators that is the problem, it's isolation between the Tx and Rx.
Multimegawatt pulses from your radar tend to raise cain with your
sensitive receiver, even if your diplexer does have 100dB isolation.

Finally, it is challenging to make something that can efficiently
radiate at a frequency while not reflecting that same frequency (i.e.
re-radiating). Brings a whole new meaning to "match at the feedpoint"
when your RCS has to be a tiny, tiny fraction of the physical size.
(for reference, the RCS of a resonant dipole with shorted feed is about
0.2 lambda^2)

As it happens I bought a nuclear submarine radio transmitter with only
a few hours on it. It is a tube version so I assume the reason that it
saw so little service was when they determined solid state was not an
issue. Just for kicks today I put together 3 rolls of 50 conductor
tape in series without unrolling them so the assembly was about 12
inches tall and 8 inches dia where as the antenna on the tower is
about the size of a bow and arrow target and good for all bands
without being frequency sensitive. Now the quick and dirty one was

really 50 wires in parallel placed in series with end fed on two outside wires. Now it was only good down to and including 20 metres while sitting on the table next to the radio in a very cluttered shack with lots of equipment and on top of that it had no shield so you can't hang your hat on those results because of proximetry effect and other short cuts taken and yet the non frequency side of it is fully evident. So for a submarine or a ship in combat the long wire would leave an observable trace even when below the surface as the long wire will rise.

Same goes for ships that have radiators in the double or triple figures where when damaged control can be transfered to other non frequency sensitive antennas. I served in the Army so I have little knoweledge as to what goes on in the Navy and thus the question posed. Certainly such a antenna would be a lot more stealth like than the water jet stream proposed on U tube or even a long wire leaving a trail on the surface for aircraft to zero upon.

Regards
Art

Yeah, but can you shower with it? See, the other antenna doubles as a
shower, just BYOS (Bring Your Own Soap.)

Regards,
JS

John, all non frequency dependent radiators have to be shielded as it
plays havoc with the cancellation of reactance. But even with the
quick lash up I made where I broke all the rules and even changed to
"stacked pancakes" instead of coils inside coils it still would be ok
for directional use in a loft for some of the bands. Either way the
lash up did not totally destroy its attributes. I suppose it would be
more impressive if I shielded it plus a reflector and put it on the
tower but that was not the point I was trying to make which is the
persistance in keeping non frequency dependentcy
while maintaining a small volume. I modeled a ten turn coil inside
another ten turn coil where both were joined together as a closed
circuit and a overall diameter of 8 to 9 inches sitting on a perfect
ground ala reflector When an antenna is not frequency dependent there
is no skin depth resistance because of the Meissner effect so more
current is applied to generating radiation. This conforming to
Maxwell's law by not indulging in generating magnetic fields. Note
Maxwell never added units of Tesla in his equation so why should you?
By the way that model showed gain inbetween 20 and 30 db because of
current bypassing the innards of the radiator and traveling on the
surface.
So the old timers were correct in saying more wire is better....as
long as you decrease the resistance
created by adding wire!!!!!! That way you have
I sq R instead of I sq R + r which is efficiency in radiation to the
maximum.by removing unnecessary losses. Simple concept eh?
Regards

motion with respect to a fix

You assume that the ether is fix. The same did Maxwell. But Maxwell did it
before MMX.
You should know (after MMX and MGX) that the ether is not fix. It rotates
with the Sun but not rotate with the Earth (it was predicted by Stokes in
1845).

>or any other aether...

They "detected no motion" with respect to Stokes ether.

> otherwise the result would have had a predictable variation due to time of
> day or
year, which was not detected.

The results of MMX and MGX prove the Stokes ether.

  Let's fix the wind problem and shorten the antenna!
Have the water spray up into a receiving vessel the distributes the water
into
5 or 6 radial tubes that make up a capacitive hat. :-)

While we're at it, let's spray out some radials for a counterpoise!

Hey, if we can catch all the water and recirculate it, then we can
add material to increase the conductivity of the water.
ok,ok I'll stop.
                                                    MikeK

Let's just fill a tube with water and provide sufficient heat-sinking to
keep the water at an acceptable temperature. Obviously, the idiot with
the sump pump and walkie-talkie realized the power of the publics'
fondness for toys ...

Regards,
JS

why don't you just go back to Opticks, thats only about 100 years
older than the almost 200 year old Stokes aether... you are still
going backwards dragging up old disproved theories.

I had a dream last night, billions of angels dancing on the head of a
pin ... it was quite unsettling!

Regards,
JS
